ENVIRONMENTAL ASSESSMENT BOARD

Ontario

ONTARIO HYDRO DEMAND/SUPPLY PLAN HEARINGS

VOLUME: 18

DATE: Thursday, May 23, 1991

BEFORE:

HON. MR. JUSTICE E. SAUNDERS   Chairman

DR. G. CONNELL   Member

MS. G. PATTERSON   Member

ENVIRONMENTAL ASSESSMENT BOARD
ONTARIO HYDRO DEMAND/SUPPLY PLAN HEARING

IN THE MATTER OF the Environmental Assessment Act,
R.S.O. 1980, c. 140, as amended, and Regulations
thereunder;

AND IN THE MATTER OF an undertaking by Ontario Hydro
consisting of a program in respect of activities
associated with meeting future electricity
requirements in Ontario.

Held on the 5th Floor, 2200
Yonge Street, Toronto, Ontario,
on Thursday, the 23rd day of May,
1991, commencing at 10:00 a.m.

VOLUME 18

INDEX of PROCEEDINGS

1   ---Upon commencing at 10:03 a.m.

2   THE REGISTRAR: This hearing is now in

3   session. Please be seated.

4   MS. PATTERSON: Just before we start, Mr.

5   Watson, I wanted to try to get clear this question of

6   reserve margin and reliability that arises from page 9

7   where we sort of disregarded those three factors. I

8   guess my question is whether you are using reliability

9   and reserve margin to mean the same thing?

10   RONALD TABOREK,
                     DAVID BARRIE,
11   JOHN KENNETH SNELSON,
                     JUDITH RYAN; Resumed
12

13   MR. SNELSON: I think we have used

14   reliability in a general sense and we perhaps should be

15   more specific in terms of exactly when we mean reserve

16   margin and exactly when we mean system minutes of

17   unsupplied energy.

18   MS. PATTERSON: I think that would be

19   helpful.

20   MR. TABOREK: In particular, it means it

21   would require you to optimize at a higher reserve

22   margin, to optimize at a higher level of reliability,

23   which would be a lower system minutes.

24   MS. PATTERSON: It seems to me, just on a

25   common sense basis, that higher reliability should lead

lower s.min.
if higher
_R.M ⸫_
higher level
_of_
reliab.

Farr & Associates Reporting, Inc.

1   to lower reserve margins.

2   MR. SNELSON: There is a cause and effect

3   here. If you want to have higher reliability, one way

4   of achieving it is to have higher reserve margins, and

5   that is one way in which things work.

6   If you are generating capacity, it

7   naturally has a higher reliability because, say, the

8   forced outage rate is low, then that may permit to you

9   lower the reserve margin and achieve the same degree of

10   system reliability.

11   So there are complex interactions here.

12   And I think that common sense does work but one has to

13   be very clear as to whether one is talking about the

14   reliability of the individual generating units or the

15   reliability of the system.

16   MS. PATTERSON: So, maybe we can try to

17   be as specific as possible throughout.

18   MR. SNELSON: Yes.

19   MS. PATTERSON: Thank you.

20   THE CHAIRMAN: Mr. Watson?

21   MR. WATSON: Mr. Chairman, before we

22   continue the cross-examination, today is the last day

23   for motions on Panel 3 interrogatories. There is one

24   outstanding interrogatory with Hydro, it's

25   Interrogatory 3.9.1, I have had discussions with Hydro

1   counsel and I have been assured that we will have the

2   answer in two weeks. It's fair to say that this is an

3   important question for ûs and we are relying on that

4   answer. I have informed Hydro counsel of this and they

5   assured me that there shouldn't be a problem getting

6   that answer within those two weeks.

7   On the assumption that that does occur,

8   and I must say, we have had good success in the past,

9   then I don't anticipate any need to come before you

10   again. But if there is a problem I just want to put

11   you on notice that we would have to come before you

12   with a motion on this paticular interrogatory.

13   MS. HARVIE: If I could just follow up

14   with that. We have answered all of the outstanding

15   Panel 2 interrogatories with the exception of three,

16   which I accept responsibility for. I held them back on

17   Monday and said that the answers ought to be fuller

18   than they were.

19   So the interrogatory that Mr. Watson is

20   referring to is a supplementary interrogatory, one that

21   his client had concerns with, we were providing some

22   further information. We have had discussions with

23   several other parties and we have some success so far

24   in resolving their concerns well. I have been advised,

25   just this morning, by Mr. Shepherd that they have a

1   number of concerns, as well and we will attempt to

2   address those in due course.

3   THE CHAIRMAN: Thank you.

4   MR. WATSON: Mr. Chairman, I don't want

5   to argue this. We are not agreeing that this is a

6   supplementary interrogatory.

7   THE CHAIRMAN: No. They said they are

8   going to answer, so I don't think we need to get into

9   that issue.

10   MR. WATSON: Yes.

11   CROSS-EXAMINATION BY MR. WATSON (Cont'd):

12   Q. Panel 2 matters from yesterday, on

13   the second last page of the transcript, that's page

14   3059 --

15   MR. SNELSON: A. I don't think we have

16   the transcript available.

17   Q. I don't think you need it because you

18   simply answered a question. "I'm sorry, I don't know

19   the answer to that question." That's at page 3059,

20   line 11 and 12. I am just wondering if we could get

21   the answer to that question.

22   MR. TABOREK: A. I can give it to you

23   right now, if you wish.

24   MR. SNELSON: A. I believe it's in an

25   interrogatory. This is the contract limits on

1   interruptible power.

2   MR. TABOREK: A. Kenneth, it's how they

3   are modelled.

4   MR. SNELSON: A. It's how they are

5   modelled, I'm sorry.

6   MR. TABOREK: A. The question is how

7   they are modelled. They are modelled similarly to the

8   hydraulic and they actually use the same module of the

9   program as an energy limited resource. And really,

10   there are a number of other energy limited resources

11   that we include in emergency measures which are, in

12   essence, modelled the same way.

13   MR. SNELSON: A. The actual terms and

14   conditions for this discount demand service which is

15   the current name of our interruptible contracts, the

16   actual terms and conditions are given in answer to

17   Interrogatory 2.6.32.

18   Q. The question that followed that was:

19   "Do you know the effect these limits would have on the

20   target reserve margin?", and you indicated that you did

21   not know the answer to that. Do you know the answer

22   now or could we get that at some future time?

23   MR. TABOREK: A. We are making a list of

24   all of those and we will answer all of those for you as

25   quickly as we can.

1   Q.   Thank you.   Yesterday you confirmed

2   that the 2,000 megawatts of off-peak was included in

3   the F&D·model inputs and you stated that the off-peak

4   energy can improve the reliability not just off-peak

5   but in on-peak hours as well, by allowing the hydraulic

6   energy to be saved for peak hours.

7   Does the modelling of this 2,000

8   megawatts off-peak in the F&D model have any effect on

9   the hydraulic modelling in the F&D model?

10   A.   Could you repeat that again, the last

11   part of your question?   Does modelling of this...

12   Q.   Does the modelling of this 2,000

13   megawatts of off-peak in the F&D model have any effect

14   on the hydraulic modelling in the F&D?

15   A.   It has to have, but any effect, what

16   do you mean by "any effect"?

17   Q.   Could you tell us what effect it does

18   have and how significant that effect would be?

19   A.   The significance, no, especially not

20   the significance.   We did calculations with and without

21   the 2,000 megawatts off-peak and my memory is - and it

22   is fuzzy - I think there was something like 2 per cent

23   involved in it.   But what I will do again is verify

24   that my memory is correct.

25   Q.   And get back to us with the answer?

1   A.   Yes.

2   Q.   Thank you, Mr. Taborek.

3   Do the results of the peak shaving depend

4   on whether or not the 2,000 megawatts is included?

5   A.   Again, I can't give you that answer.

6   Q.   You will get back to us?

7   A.   Yes.

8   Q.   Thank you. Do you know if the model

9   just simply adds the 2,000 megawatts of off-peak energy

10   to the available hydraulic energy before it does the

11   peak shaving?

12   MR. SNELSON: A.   I wouldn't expect it

13   to. I think Mr. Taborek yesterday indicated that it

14   was modelled as a generator. And if that was correct,

15   then that isn't the same as adding it to the hydraulic

16   energy.

17   MR. TABOREK: A.   Again, I think, an

18   undertaking.

19   Q.   You will check all that and get back

20   to us?

21   A.   Yes.

22   Q.   Is there a document that describes

23   all of this, a manual or paper or something?   ...

24

25

1   [10:14 a.m.] A. Well, you have our most recent

2   manual.

3   MR. WATSON: Okay, thank you.

4   Mr. Chairman, Members of the Committee

5   and the Panel, I'm still dealing with the global area

6   of reserve margin. I'm turning to a new subarea of

7   incapability factors in that main area.

8   Q. Panel, if you'd look at page 22 of

9   Exhibit 137, that is page 7 of the F&D manual. Page 7

10   presents some formula dealing with the F&D model and

11   its calculation of unavailability factors for the

12   two-state model. One of the variables in there is FOR,

13   that is F-O-R. Where do the values of FOR come from?

14   MR. TABOREK: A. FOR is forced outage

15   rate, and these values would come from annual forecasts

16   of reliability indices that we prepare, and the last

17   three years of these reports have been introduced as

18   evidence. I don't have the numbers in -- excuse me,

19   have been in interrogatories, provided in

20   interrogatories.

21   MR. SNELSON: A. They were provided in

22   interrogatory 2.7.1. That was the 19 -- sorry, not

23   2.7.1.

24   Q. 2.7.81.

25   A. 2.7.40, sorry, 2.7.40 provided the

1   March '89 and the January 1990 versions.

2   Q. And the '90 was just put in the other

3   day?   .

4   A. The '91. The early -- January or May

5   '91 edition, which was current, was put in evidence

6   just the other day.

7   Q. Which is the '90 forecast?

8   MR. TABOREK: A. Yes, the numbers, every

9   report is prepared in the fall of the year, October,

10   November.

11   Q. Yes.

12   A. So the '90 report would have been

13   prepared in the fall of '90, and it is usually issued

14   in the early part of the next year. So it is the

15   report dated '91. That would be common to all three

16   reports.

17   Q. In those reliability forecasts, for

18   instance, in the '89 reliability forecast, tables 1 and

19   2 deal with DAFOR, D-A-F-O-R.

20   A. Yes.

21   Q. Are the DAFORs the values used here

22   for FOR?

23   A. Yes.

24   MR. SNELSON: A. I would just want to

25   just caution you a little bit. That is, this is the

1   manual as it was in the late 1970s. It doesn't

2   necessarily correspond exactly with our current

3   practice. So, the measure of forced outage rate that

4   we currently use is DAFOR, D-A-F-O-R, as it is in the

5   reliability indices reports that you have. The way in

6   which they are combined together may have changed a

7   little since the late 1970's. So, I wouldn't be

8   prepared to accept these formally, exactly as they are,

9   as being a current practice.

10   Q.   This manual, though, is all we have

11   right now?

12   A.   Yes.

13   Q.   So, I guess we are forced to work   /

14   with this right now.

15   Could you provide us with the updated

16   formula?

17   A.   If there is a change in this formula,

18   we will provide it.

19   Q.   I got the impression from what you

20   were saying that there was a change.

21   A.   I see these factors like 7 over 5 and

22   7 over 2, and ratios like POSMOF, which I don't think

23   are currently forecast. So, I suspect that this

24   formula isn't exactly applicable.

25   MR. TABOREK: A. Having cautioned you

1   that we are going back and reading things that were

2   written 14 years ago, one of the things that I may be

3   able to say is that what this formula does is, it does

4   two things to us. It is first of all a mechanism to

5   allow in-service data uncertainty to be included in the

6   model or not, and so some of these are switches to

7   allow that to happen, in effect - to allow the

8   computation to be done one way or another.

9   Now we almost always use in-service data

10   uncertainty, the other thing is that we also have a

11   factor called MOF, maintenance outage factor, which is

12   a degree of maintenance over which you have some

13   limited degree of time in which to schedule. And it

14   could be scheduled beyond the next weekend. It need

15   not be done immediately. So, there are three things,

16   F-O-Rs, which are DAFORs and DAUFOPs have to be done

17   immediately. MOFs you have beyond the next weekend in

18   which to schedule it, and then POFs you have quite a

19   large time, planned outage factors, a long time to

20   schedule it.

21   What the MOFACT parameter does, it is a

22   switch that allows you to shift MOFs to the weekends or

23   not. And we always switch MOFs to the weekend. So,

24   some of this is, in effect, still used, but not

25   necessarily all of it just that way.

1   Q. You were referring to the forecasts.

2   In the forecasts you also take care of DAUFOPs and

3   UFORs, I believe -- UFOPs.

4   A. UFOPs, which get carried into

5   DAUFOPs.

6   Q. Could you say that again, please?

7   A. I think, to go into English -- my

8   colleagues said they would have my head if I got into

9   MOFs, POFs and DAFORs.

10   It is important for us to know, to be

11   able to categorize the outages that occur with our

12   generating units. And we have quite an extensive list

13   of outage categories, about a dozen or so, that are

14   described in the reports. The ones that really matter

15   are the ones that I really described to you to this

16   point, the ones that matter here in this hearing.

17   There are those which are forced on you which must be

18   dealt with right now. Those are the ones that affect

19   reliability.

20   Then there is a category called

21   maintenance outage factors, MOFs. These are the ones I

22   described, where you have some limited flexibility in

23   scheduling them, typically beyond the weekend, and the

24   precise definitions are in this.

25   Then, there are the planned outage

1   factors, which are the ones that could be extended, can

2   be fitted in over some longer period of time.

3   The sum of those, simply speaking, is the

4   incapability of the unit; how much time the unit is out

5   as a whole.

6   I showed you graphs earlier of the

7   behaviour of the nuclear, fossil and hydraulic systems,

8   and I just simply labeled them "Forced" and "Total."

9   The "Forced" was the forced outages, and the "Total"

10   was force plus MOFs plus POFs. Force plus maintenance

11   plus planned for the total.

12   The importance of those, the forced

13   outages impact reliability because they hit you right

14   now, and the total influences your maintenance

15   requirements and your energy output from your system.

16   So, it is important in energy. Plus you have to find

17   time to do it all, which could influence your forced

18   outages.

19   Those are the three broad categories.

20   Now within forced there is, again simplifying, two

21   categories. There is DAFORs, and what -- the FOR is

22   forced out, the DAFOR is derating adjusted forced

23   outage, and all it means is that sometimes you are not

24   taken out totally, you are only taken out partially, so

25   there is an adjustment made for that.   ...

1   [10:25 a.m.] You don't lose all; you lose some of your

2   units. So, it is a DAFOR, not a FOR. And that

3   parameter is used when the unit is running almost all

4   the time and it is forced out.

5   But some of our units are peaking units

6   and they basically sit unused until called upon. And

7   so, what is important is not whether it fails when you

8   don't need it, but whether it fails when you need it.

9   And so now they make an adjustment to the forced outage

10   rate, UFOP, I think - utilization forced outage

11   probability. What are the chances of that thing that

12   has been sitting there unused coming on when you want

13   it, which is the appropriate criteria for peaking

14   units?

15   And then, there is the DAUFOP, which is

16   the derated - introducing the derating aspect of that.

17   And that the FORS here would normally be DAFORS and

18   DAUFOPS. It is simply forced outages.

19   MR. SNELSON: A. This is explained at

20   the back of the reliability indices reports that were

21   given in answer to that interrogatory, if it was

22   necessary. That is Interrogatory 2.7.40. If it was

23   deemed necessary to get into this degree of detail, but

24   we are going to a tremendous level of detail, I think,

25   for the issue we are trying to talk about.

1   MR. TABOREK: A. And this particular

2   question and this particular piece of the code, when

3   you have a thing called -- when you have this MOF which

4   you may or may not shift a short time, to use it, you

5   would have to have in your computer code a little

6   switch to say, am I going to shift it or not? And that

7   is what the MOFACT is; it is a switch for that.

8   Q. What is the POSMOF?

9   A. It is defined in the computer code.

10   You have the manual; it is defined in the manual.

11   MR. SNELSON: A. It is, in fact, defined,

12   I believe, on that page that you have under Item 5 at

13   the very top.

14   MR. TABOREK: A. Yes, okay.

15   Q. Well, it says, "Fraction of

16   maintenance outage that will be considered."

17   MR. SNELSON: A. Yes.

18   Q. I am not sure that helps us an awful

19   lot. Could you expand on that?

20   MR. TABOREK: A. To be shifted.

21   Q. From when to when?

22   A. From now until the weekend.

23   Q. To the next weekend? To any

24   particular weekend?

25   A. You are taking me into a level that I

1   don't normally go to into the code. I think I would

2   come back.

3   You have to say two things about

4   mathematical models for generation reliability: One is

5   that people have done some extremely sophisticated work

6   on them to attempt to model very rare events occurring

7   on a complex system, and they set up many cases, many

8   things.

9   But having said that, these models have

10   definite limits in the degree to which you should rely

11   on your output. And again, the output is very much

12   dependent on the sense of the input and the way in

13   which you choose to use some of these parameters.

14   And so I think that --

15   THE CHAIRMAN: Perhaps it would help a

16   bit - for me, at least - if you explain, Mr. Watson,

17   just where this particular line of cross-examination is

18   directed towards. What you are attempting to

19   demonstrate by it?

20   MR. WATSON: Well, what we are trying to

21   do, Mr. Chairman, is, again, look at what the F&D model

22   is doing with respect to capability factors. And Mr.

23   Snelson said something of interest; he said he didn't

24   expect to get into this level of detail, and maybe that

25   is going to be a clue for me, because later on when we

1   leave reserve margin, there is a whole area that I

2   would suggest is of significance in dealing with the

3   existing system, and that is the plant performance of

4   the existing system. And needless to say, the only way

5   you can properly address that is to get into the

6   capability factors, and I was anticipating doing that

7   in some depth.

8   Now, if this is not going to the

9   appropriate panel to deal with this, I would like to

10   know when I can deal with it, because I would suggest

11   to you the capability factors of the various plants are

12   of very great importance in a planning exercise for a

13   host of reasons; just one right off the bat is to

14   determine, for instance, your level of base load that

15   you need and the units that are going to satisfy that

16   base load.

17   MR. SNELSON: I believe on this panel, we

18   are prepared to deal at a general level with

19   predictions of availability and how that affects the

20   reliability level in a general sense. As to the

21   details of those predictions, whether a particular

22   generating unit in the year 1996 will have a capability

23   factor of 80 per cent or 85 per cent, then we would

24   expect that that degree of detail would be discussed by

25   the appropriate option panel.

1   So, we would expect that the details of

2   thermal plant availability would be discussed in Panel

3   8 and the details of nuclear availability would be

4   discussed in Panel 9, and the details of hydraulic

5   availability would be discussed in Panel 6.

6   But obviously from a planning

7   perspective, we are interested in the total

8   availability, which, of course, is made up of details.

9   The primary thing that effects the planning of the

10   system is the total availability of the components of

11   the system.

12   MR. WATSON: I will try and work within

13   that and perhaps as we proceed we will get some idea of

14   exactly where the envelope is and we can decide what we

15   will deal with here and what we will deal with in the

16   future.

17   Q. Mr. Taborek, I believe you indicated

18   that MOFACT was a switch, if you will. Is that the

19   word you said?

20   MR. TABOREK: A. I will look up the

21   definition. Oh, I am sorry, I am looking at the

22   wrong -- MOFACT, yes, it is a switch.

23   Q. That means it is either on or off.

24   It has a zero/one value?

25   A. Well, I guess it -- oh, I am sorry.

1   MR. SNELSON: A. If you look at the

2   previous page, the one that you referenced, and I have

3   the whole exhibit in front of me.

4   Q. Yes.

5   A. If you look at page 6 of that

6   document, and I don't recall how it is referenced in

7   the hearing as to whether it is an interrogatory or --

8   THE CHAIRMAN: It is 141, I think; is

9   that right?

10   MR. WATSON: Yes, it is.

11   MR. SNELSON: Okay. Then on the

12   preceding page, which is page 6, there is a sub item,

13   small Roman numerals iv, 4, which indicates that the

14   maintenance outage factor, MOFACT, is specified in

15   input data. The MOFACT is the fraction of maintenance

16   outage - an MOF, maintenance outage factor which is

17   performed on the weekdays. One minus MOFACT is the

18   amount that is postponed to the weekends.

19   MR. WATSON: Q. So it is not a switch

20   then?

21   MR. SNELSON: A. If it was --

22   MR. TABOREK: A. Well, it is a switch if

23   you set it to zero and that is the way we use it as we

24   transfer all the maintenance. I was going to say it is

25   a parameter that you could set to any value. We use it

1   as the switch by setting it to zero.

2   That is why I went back to say, putting

3   it in this way, people can use these things in

4   different ways, to achieve various results that the

5   program might not otherwise do. That is why I made

6   that statement.

7

22

23

24   ...

25

1   [10:35 a.m.] MR. SNELSON: A. This, I believe, is a

2   very small point.

3   Q. Unfortunately, I don't have your

4   expertise in this area, Mr. Snelson, that's why we have

5   to ask these questions, and, hopefully, as we go

6   through them, we will determine the significance.

7   MR. TABOREK: A. For us, we usually set

8   it zero and all the MOF is transferred to the weekends.

9   Q. Is it POSMOF set to zero; is it a

10   switch as well? It's also a fraction.

11   MR. SNELSON: A. We can take an

12   undertaking on that, because I don't think either of us

13   know the answer to that question and we would just be

14   spinning our wheels to try and answer it.

15   MR. TABOREK: A. If I may, actually, if

16   you look at the formula, and if you set MOFACT equal to

17   zero, then it doesn't what matter what POSMOF is

18   because the whole bracket that it is in is going to be

19   equal to zero, I think, or is...

20   MR. SNELSON: A. No. It appears in the

21   next formula.

22   MR. TABOREK: A. So, in the weekend,

23   it's going to come off in the weekend one.

24   MR. SNELSON: A. I think we should

25   merely give you the undertaking and get back to you on

1   that.

2   Q.   Thank you.   You mentioned MAF as

3   well, monthly availability factors.   Where do these

4   values come from?

5   A.   I don't know.

6   Q.   You will get back to us on that.

7   And, also, could you get...

8   A.   If it is necessary we will get back

9   to you on it, yes.

10   THE CHAIRMAN: Well, he thinks it is

11   necessary, and so I guess it is.   That makes it

12   necessary.

13   MR. SNELSON: Fine.

14   MR. WATSON: Thank you.

15   Q.   And again, if you could get back to

16   me on this question, as well.   I am interested in the

17   whether MAF reflects variations in monthly availability

18   owing to planned outages only, or are other outages

19   accounted for, as well?   And then, the third question

20   would be: Where does the planned outage schedule on

21   which this is based come from, for the short term and

22   the long term?   Thank you.

23   MR. TABOREK: A.   Yes.

24   Q.   The F&D model requires input values

25   of average repair time for each generator.   Do these

1   values come from the average forced outage duration

2   table on page 31 of the '89 forecast reliability?

3   A.   There are two.   There is a statement

4   and a question you made.   The model doesn't always

5   require the duration of outages.   It depends on what

6   you wish to calculate with the model.

7   If you are going to calculate duration of

8   outages, yes, but if you are only going to calculate

9   unsupplied energy, it doesn't.   And as to where the

10   data comes from, it is typically recorded in, again,

11   the forecast of reliability indices and you have the

12   page on page 23 of your exhibit.

13   Q.   That's page 31 of the '89 forecast

14   which is page 23 of Exhibit 137.

15   A.   Yes.

16   Q.   I did a quick check and it looks as

17   though the '90 forecast has exactly the same page.

18   A.   That's correct.

19   Q.   With exactly the same numbers.

20   A.   That's correct.   If I may, I will

21   just explain that, unless you're going to ask about it?

22   Q.   Please go ahead.

23   A.   Okay.   The information ahead on this

24   chart indicates that this chart is not updated

25   frequently.   Basically, we have not felt comfortable

1   with that portion of the model that deals with the

2   calculation of durations and consequently we have

3   tended not to use it.

4   It is not necessary to do our

5   calculation. When we calculate expected unsupplied

6   energy we only need the forced outage rates because

7   it's that that you use in the economic optimization.

8   And because we weren't comfortable with what the model

9   was doing, we basically have not asked for those number

10   to be kept up-to-date.

11   Q. When you say you are not comfortable,

12   would one of the reasons you are not comfortable

13   include the fact that in the first sentence you are

14   only dealing with outages which last for more than 30

15   minutes and less than four weeks with deratings

16   ignored?

17   A. Yes, and you can get some long

18   outages, yes. That's one of the reasons.

19   Q. That's one of the reasons you are

20   revisiting all of this?

21   A. That is a data problem, but some of

22   our discomfort is also with the working of the model.

23   Q. Yesterday we were talking about the

24   higher reserve margin which is attributed in part to

25   the immature nuclear units. Do you recall that

1   discussion?

2   A.   Yes.

3   Q.   The reference is page 95 of the

4   reliability review for 1991. Now, does this arise from

5   higher values of DAFOR, MOF and POF in Table 16 of the

6   '89 forecast reliability?

7   A.   Well, the effect on reliability is in

8   the DAFOR. Unless the MOFs and POFs get so large --

9   well, they don't. I won't go any further.

10   MR. SNELSON: A.   I think we did indicate

11   yesterday that there was a second effect, which is the

12   modelling of in-service date uncertainty, which has an

13   additional effect of indicating a lesser availability,

14   effectively, of units very close to their in-service

15   date.

16   Q.   So that there are two effects?

17   A.   Yes.

18   Q.   Do the commissioning tests occur

19   during or before the first years of the table, which is

20   is Table 16 at page 24 of Exhibit 137? That's the

21   forecast of reliability indices for the future nuclear

22   stations, Table 16.

23   THE CHAIRMAN: What is the source of that

24   table? I'm sorry.

25   MR. WATSON: That's the 1989 forecast of

1   reliability indices.

2   THE CHAIRMAN: And what exhibit is that?

3   MR. WATSON: I am not sure that is an

4   exhibit.

5   MR. TABOREK: It's again in Interrogatory

6   2.7.40.

7   MR. WATSON: I can make that an exhibit

8   right now.

9   THE CHAIRMAN: No, no. I am just making

10   a note of where the source is because sometimes it is

11   helpful to look at the other pages in the document.

12   MR. WATSON: The Clerk has copies, so we

13   can make it an exhibit right now, if you like.

14   MS. PATTERSON: We have copies attached

15   to Interrogatory 2.7.40; right?

16   MR. WATSON: Yes.

17   THE CHAIRMAN: All right; that's good

18   enough.

19   MR. SNELSON: I think the answer to your

20   question as to whether the commissioning tests precede

21   these forced outage rates is that the forced outage

22   rates apply from the commercial in-service dates of

23   units, and the commissioning tests precede those

24   in-service dates.

25   MR. WATSON: Q. So, it would be before

1   then, it would be before the dates in these tables?

2   MR. SNELSON: A. Yes, these data apply

3   from commercial in-service.

4   Q. Just quickly, could you confirm that

5   the inputs used in the F&D model for the analysis

6   presented in the '91 reliability review came from the

7   '89 forecast?

8   MR. TABOREK: A. That is correct.

9   Q. As opposed to '88 forecast?

10   A. That is correct.

11   Q. What figures were used in the DSP,

12   the '88 figures?

13   MR. SNELSON: A. The analysis you are

14   referring to would be the reliability analysis that is

15   in the plan analysis document on some preliminary cases

16   for the DSP. And I presume that would be the values

17   prepared in late '88 and published in early '89.

18   MR. TABOREK: A. There is usually a

19   listing of assumptions. Here we are. Yes, on page

20   3-15 of the plan analysis, I am not sure what exhibit

21   it is -- Exhibit 6, generating unit data, 1988 forecast

22   of reliability indices.

23   Q. When Mr. Snelson was answering that

24   question, he indicated that was used for some

25   preliminary plans?

1   A.   Yes.

2   Q.   Are you saying that this was now done

3   more generally?

4   A.   No.   I was describing the preliminary

5   plans.   The sequence here is that as we got into the

6   Demand/Supply Plan exercise and before we knew the

7   outcome of the Demand/Supply Plan, we went through our

8   reliability process to take our 25 system minute

9   criterion converted to reserve margins.   We did that

10   and we then used those reserve margins to develop the

11   plans.   And it is that initial process that is

12   described in Chapter 3 of the plan analysis.

13   Since then, time has passed on the one

14   hand, numbers have changed, and on the other hand we

15   have for information, we have completed the planning

16   process and we have more information about the future

17   and so we have redone the calculations and that is

18   reported in Exhibit 87, the reliability review that we

19   have been talking about.

20   So it's those two pre-DSP, post-DSP

21   reliability calcs, and then we often talk about a 1981

22   set of calcs sort of earlier on, that's reported in the

23   another exhibit.   So, there are three time periods in

24   which these were done.

25   Q.   The '89 values were used for 1991

1   reliability review. Can you tell us what the impact

2   would be if you had used the 1990 figures in that

3   reliability analysis?

4   A.   There is a small increase in the

5   forced outage rates in 1990 compared to 1989. It

6   varies with time and there is not much difference

7   between the '88 and '89 numbers.

8   I think I may be able to show you. I

9   will have to show you three stages, because it's

10   different for each of the types of generation.

11   Q.   Mr. Taborek, I don't want to

12   interrupt you; we can read the forecast to determine

13   what the actual numerical differences are--

14   A.   Okay.

15   Q.   --in the values. I was more

16   interested in what the bottom line would be, what is

17   the overall difference in reliability and reserve

18   margin?

19   A.   I am sorry I can't give that to you

20   right off. Because the forced outage rates were

21   slightly higher, running it now other things being

22   equal, would cause a small increase in the required

23   reserve margin.

24   MR. SNELSON: A. There is a way of very

25   roughly estimating it and that is that if forced outage

1   rates are in total -- if 1,000 megawatts of plant has

2   an increase in its forced outage rate by one per cent,

3   then that will create a need for somewhere around 10 or

4   12 megawatts of additional reserve. It's a little·bit

5   higher than the one per cent of the 1,000.

6

7

8

9

10

11

12

13

14

15

16

17

18

19

20

21

22

23   ...

24

25

1   [10:50 a.m.] Forced outage rate on average, you lose

2   one per cent of your capacity, then the effect on

3   reserve margin is just a little bit larger than that

4   one per cent of the capacity. So there are rough

5   estimations that can be made.

6   Q. Thank you. And no doubt you will be

7   doing that analysis, and if, in fact, your rough

8   estimate is incorrect, you will let us know?

9   MR. TABOREK: A. Well, these -- we

10   wouldn't actually redo our analysis for just the reason

11   of one forecast changing. I mean, forecasts change all

12   over the place, all the time. You can never stop

13   rerunning your models. It is what you expect, and it

14   is what the margin is for.

15   You are really looking for quite large,

16   significant changes and often several of them, so that

17   you are getting a really significant input, rather

18   than, in effect, forecasting variations.

19   Q. Could we leave it this way then?

20   Could you look at it tonight, and if, in fact, it is

21   something substantially different than the one per cent

22   you were just telling us, that you will let us know?

23   MR. SNELSON: A. My one per cent was an

24   example. It wasn't indicating that there was a one per

25   cent increase in forced outage rate. All I was saying

1   is that if you read the previous forecast and compare

2   it with today's forecast, and for each generating plant

3   you take the change in average availability due to the

4   change in forced outage rate, and you add them all up

5   and add a little bit, you will get the approximate

6   effect on reserve requirement?

7   MR. TABOREK: A. You can just look at

8   the three reports, measure the differences and apply

9   that factor, and you will have it.

10   Q. Let's do it this way then. If you

11   could look at it tonight, then let us know tomorrow

12   what, in fact, the difference would be if you used the

13   '90 numbers instead of '91. I'd appreciate that.

14   A. We may be able to provide you an

15   estimate. It wouldn't be a calculation.

16   Q. An estimate is fine.

17   One last question, before I leave this

18   area. What would be the impact on figure 5.1 of

19   changing the reliability indices from the '89 values to

20   the '90 values?

21   A. The sloping line, which is, in

22   effect, reflecting the unsupplied energy which shift to

23   the right, --

24   Q. Which shift to the right?

25   A. To the right.

                    Farr & Associates Reporting, Inc.

1   MR. SNELSON: A. If the forecast rate

2   outage rates were higher.

3   MR. TABOREK: A. Which would cause you

4   to optimize at a higher reserve rate.

5   Q. Thank you. I'd like to move on to

6   another area of load factor.

7   Does the F&D model use as an input a

8   24-hour load shape for a typical day, or only a daily

9   peak?

10   A. What it does is it utilizes three

11   load shapes: One for weekdays, one for Saturdays, one

12   for Sundays for each month, so three per months, times

13   12 months for 36 months. So, it is 36 load shapes.

14   And then it utilizes a duration curve of peaks for each

15   of those load shapes, I believe. Yes, a duration curve

16   of peaks for each of those load shapes.

17   MR. SNELSON: A. The daily load shapes

18   Mr. Taborek refers to, do have 24 hours in them. So,

19   they are the full load shape for the day, not just peak

20   hour of the day.

21   Q. If you could refer to page 25 of

22   Exhibit 137, which is page 58 of the 1991 reliability

23   review...

24   THE CHAIRMAN: That is '87, is it?

25   MR. TABOREK: Yes.

1   MR. WATSON: Q. You see the second last

2   sentence on that page reads:

3   "For example, using the simplified

4   LOLE technique mentioned earlier in this

5   chapter, it was found that decrease in

6   the ratio of average daily peak to

7   monthly peak by five per cent results in

8   about a five per cent decrease in reserve

9   margin requirements."

10   Could you tell us how that sensitivity

11   analysis was done?

12   MR. TABOREK: A. We were attempting to

13   get a rough cut at the effective load factor on reserve

14   margin, and, essentially, it took some normal

15   distributions and attempted to modify them to reflect

16   the load factor. That is what is reported here.

17   Now when you flag this, I think there is

18   something strange here. This number seems too large to

19   me.

20   Q. Which number is that?

21   A. That a five per cent change in load

22   factor would cause a five per cent change in reserve

23   margin. So, what I'd like to do is go back and take a

24   look at this.

25   Q. Thank you. If you could do that and

1   then let us know either this afternoon or tomorrow. I

2   was going do ask you a series of questions on that--

3   A.   Oh, okay.

4   Q.   --with respect to whether -- well, I

5   won't get into them now. Why don't you...

6   A.   We will elaborate on the information

7   we give you then.

8   Q.   Well, perhaps I could ask you this.

9   These were, in effect, a series of methodological

10   questions. Would you be in a position to answer those?

11   A.   It is difficult to answer your

12   question as posed, since I don't know what they are.

13   The easy ones, yes.

14   Q.   Tell you what, why don't we defer

15   these questions until you can get back to us with a

16   correction for that statement?

17   Just before we leave that, can you give

18   us some idea of what your discomfort is with that

19   statement?

20   A.   It looks too high.

21   Q.   There are two fives.

22   A.   The two fives, yes.

23   Q.   Both those fives look too high?

24   A.   Well, no the first five is an input

25   in effect, and it is the output five, the second one,

1   that looks a bit high.

2   Q. What would you think it ought to be?

3   A. I'm not in a position to say at the

4   moment, but I will be shortly. When they pointed it

5   out, I set some work going on it.

6   Q. How are the inputs, the load shape

7   inputs to the F&D model, constructed?

8   A. The load shape inputs. Well, we

9   would have -- no, I think rather than attempt to answer

10   generally, I will take that under advisement.

11   Unless... Ken?

12   MR. SNELSON: A. I can remember, in

13   general, how it is being done. And that is it is being

14   done by analysis of actual load shapes from past data.

15   And so we do, from time to time, recalculate the load

16   shapes based on an analysis of actual load data for

17   historical years.

18   Q. In addition to the day types, I

19   believe yesterday you mentioned scaling factors, 101

20   scaling factors, did you not? Regardless of whether

21   you did or not...

22   MR. TABOREK: A. Yes. I didn't think I

23   did.

24   Q. Could you tell us how these 101

25   scaling factors, how are they representing the

1   probability distribution of peak demand within each day

2   type which is constructed?

3   A.   Basically, we will take -- the day

4   types are normalized, and then...

5   Q.   Normalized to?

6   A.   To a unit. So you are quite right

7   then. The peaks then come from the peak duration

8   curve, and they are basically determined by using five

9   years of data for that day type, to give -- and since

10   you are doing this for every month, and there are, say,

11   twenty weekdays in a month, and you take five years of

12   information, you get roughly a hundred points on your

13   duration curve, a hundred and one.

14   Then the weekends, there are not that

15   many days, so you have fewer points, but we interpolate

16   to around a hundred. And then those factors are

17   applied to the normalized load shapes.

18   Q.   Do those factors represent

19   weather-related load uncertainty or long-term load

20   uncertainty or both?

21   A.   Those factors don't.

22   Q.   Are there factors which do?

23   A.   The load forecast uncertainty is

24   introduced in addition to that, and it is the load

25   .   forecast uncertainty that includes the latter two items

 1   that you mentioned.

 2   Q. We were talking about the probability

 3   distribution when we were discussing the scaling

 4   factors. Are these distributions the same for each

 5   month within the year?

 6   A. No, they would be different for each

 7   month, I believe, because you pick the days appropriate

 8   to the month, and you have one for each load shape.

 9   Q. Based on the historical data?

10   A. Historical data, yes.

11   Q. And actually the same answer would

12   apply with respect to year to year data as well? You

13   are not assuming same distributions each year, you

14   are...

15   MR. SNELSON: A. In the future, we

16   generally have no reason for saying that the

17   probability distribution of peak loads will be

18   different, say, in 1996 to what it will be in 1997.

19   So, the shape of the curves will be the same for each

20   year, but the peak of the curve will be adjusted to the

21   peak load in the load forecast to account for load

22   growth. So, all the shapes generally stayed the same

23   after the future, but they are scaled up according to

24   the forecast of load growth.

25   Q. Mr. Snelson, you mentioned yesterday

1   the LMSTM model. Are the same load shapes used in the

2   F&D model as used in the LMSTM model?

3   A. No.

4   Q. How are they different?

5   A. The structures of the models are

6   different, and therefore they require different

7   definitions of load shape.

8   Q. You mentioned that the F&D model

9   derives its input for this area from historical data.

10   Does the same data set supply the input to the LMSTM

11   model. The LMSTM model is also based on historical

12   data and analysis of historical data.

13   Q. So it is the same data set, just

14   different inputs are created?

15   A. I cannot be definite that it was the

16   same years of historical data that were used as the

17   basis.

18

19

20   .

21

22

23

24

25   ...

1   [11:04 a.m.] MR. TABOREK: A. And a special feature

2   of LMSTM is it uses data by different classes of load

3   and it builds load shapes. And so it is quite a

4   different model.

5   Q. Would it be appropriate to use an

6   end-use model to determine the load shape for a

7   reliability model?

8   A. Well, you would have to say it

9   depends.

10   Q. On?

11   A. On the model, the data, the job you

12   are doing.

13   MR. SNELSON: A. It depends on whether

14   you have enough data about the characteristics of the

15   end uses to be able to combine them together in a

16   useful way. I think that in Panel 1, the indication

17   was that the end-use load forecasting model is

18   primarily an energy model and that they are proposing,

19   I believe, to do some work to enable it to forecast

20   peak loads as well.

21   To actually be able to make it useful for

22   a reliability model, you would not only have to be able

23   to forecast the peak load, but you would also have to

24   be able to forecast the variability of the peak load.

25   So, I think that the end-use models that

1   we currently have are, at least, two major development

2   stages away from being able to be used for a

3   reliability analysis.

4   Q.   Is it fair to say that system load

5   factor is related to the load factor of the three

6   sectors; that is industrial, residential and

7   commercial?

8   A.   That is one way of describing it.

9   Q.   Is it also fair to say that, as the

10   load factors for the three sectors change, so does the

11   system load factor?

12   A.   Presuming the changes are not

13   offsetting, yes.

14   Q.   I understand that, currently,

15   industry has a high load factor and residential has a

16   low load factor.

17   A.   Certainly a lot of industry has a

18   high load factor. I would presume that the other

19   classes have lower load factors, but I haven't looked

20   at the data recently.

21   Q.   I also understand from Panel 1 that

22   the Hydro load forecast department has forecasted

23   changes in the various sector load shares. If that is

24   correct, how is that accounted for?

25   A.   What is accounted for in our models

1   is the energy demand that is forecast in the load

2   forecast and the peak demand that is forecast in the

3   load forecast. And those to two things define load

4   factor.

5   I am sure there has been considerable

6   discussion with Panel 1 as to their methods of coming

7   up with their peak and their median load forecast.

8   Q. How does that relate to you? The

9   load forecasting people do what they do; how does that

10   relate to you people?

11   A. We use load shapes, peak load

12   duration curves, so as to match the peak forecast of

13   the load forecast and to match the energy demand of the

14   load forecast.

15   Q. What is the smallest unit of time in

16   the F&D model? Is it one hour or 20 minutes?

17   A. One hour.

18   MR. TABOREK: A. With one modification:

19   We enter 20 minute loads, but there is a pre-processing

20   program that converts them to hour and so it uses one

21   hour.

22   Q. Okay. If it uses one hour, how does

23   it handle the 20-minute system peak that we have heard

24   so much about?

25   A. By using an equivalent one hour. And

1   the difference, incidentally, between the 20 minute and

2   the one hour is fairly small. I think it is about 200

3   megawatts, if my memory serves me right.

4   MR. BARRIE: A. Perhaps I could add,

5   yes. In response to the question earlier, we did some

6   analysis on the difference between instantaneous

7   20-minute and one-hour peaks. It depends on the

8   particular day, of course, so it can vary, but the

9   difference between 60- and 20-minute would appear to be

10   somewhere between 50 and 250 megawatts, depending on

11   the particular day.

12   I could add as well, the difference

13   between instantaneous and 20-minute. Although we don't

14   record instantaneous all the time, we have visually

15   seen it, and we would suggest that the difference there

16   is somewhere between 50 and 150 megawatts, depending on

17   the peakness of that particular day's operation.

18   MR. TABOREK: A. To put that in

19   perspective, those are parts of about 24,000 megawatts.

20   Q. So, for each hour you use a 20-minute

21   number?

22   A. No, no. I think I am just outlining

23   for you the process by which data is prepared for the

24   F&D model. And I think you may have seen written up in

25   the manual the fact that 20-minute peak data is input.

1   Well, it is quite true it is input, but

2   there is a processing module that converts it to hourly

3   peaks and the hourly peaks are actually used in the

4   calculation. That is why I wanted to make that

5   distinction.

6   Q. Panel, if you could turn to page 26

7   of Exhibit 137.

8   And Mr. Chairman, I am now turning to

9   some questions on the environmental limitations, which

10   are at Section 4.7 of page 83 on Exhibit 87. And what

11   you will see on that page are a number of environmental

12   limitations that might impact reliability are

13   mentioned. They include reducing the net output of

14   generating units, increasing the forced outage rate of

15   fossil-fired units, forcing several units out of

16   service leading to transmission constraints resulting

17   from abnormal operation of the system during air

18   pollution episodes.

19   Can any of these situations arise under

20   existing regulations?

21   A. Yes, they can. The first item, for

22   instance, reducing the net output of generating units,

23   Ms. Ryan mentioned that we had installed devices called

24   flue gas conditioners on our major fossil plants. The

25   purpose of these devices is to allow the precipitators

1   which remove dust from the flue gas to operate as well

2   with a lower sulfur coal that we were using to reduce

•3   acid gas emissions as they do with the higher sulfur

4   coal for which they were designed. We were pushing

5   them beyond their design so we were augmenting them

6   with this new technology.

7   And so the output of a generating unit is

8   limited by an opacity limit, which Ms. Ryan again

9   defined.

10   Now, we had trouble getting those flue

11   gas conditioners to work properly. And for some period

12   of time -- your recourse then is to derate the units

13   so that they are not sending up as much dust so that

14   the precipitator is working not as proposed, would be

15   able to stay within the opacity limits.

16   So, in order to meet the present emission

17   limit and opacity limits, the present opacity limits,

18   we had to suffer a derating until such time as we got

19   those devices working properly.

20   Q.   Are there any other examples?

21   A.   Now, the present, with the same

22   regulation as we now have or really any SO(2)

23   regulation, we are now going ahead, as Ms. Ryan again

24   described, fit two scrubbers on Lambton, and other

25   scrubbers are featured in our plans.

1   The scrubber is, in effect, a large

2   factory, a chemical factory, and a chemical factory

3   requires power to run and it basically takes that power

4   from the generator that it is cleaning and reduces the

5   available power of that generator by roughly one per

6   cent, I think, but that is recorded somewhere in these

7   pages close behind. And again, depending on this type

8   of scrubber, anywhere from .9 to 1.5 per cent of the

9   power output of the generator is required to run the

10   scrubber.

11   Q. You have described a couple of

12   situations, Mr. Taborek. Has Hydro done any analysis

13   to evaluate the potential impact of these existing

14   regulations on system reliability?

15   A. When you use the words "any

16   analysis," it is a little bit too broad to answer.

17   Q. Well, can you just --

18   A. Could you narrow that down a bit,

19   please?

20   Q. Can you tell us what Hydro has done?

21   (Laughter) I am not trying to be facetious.

22   A. Okay. Basically, the reason I am

23   hedging is you can't analyze anything without analyzing

24   reliability impacts. You have to look at reliability,

25   energy, cost, et cetera. You always look at all of

1   them at all the same time. But if you say, did we do

2   special F&D runs to determine the impact of scrubbers

3   on reliability, no, we didn't.

4   Now, what we did do is, we introduced the

5   effect of scrubber unreliability into the forced outage

6   rates of the fossil generating units. And we also,

7   when we do our calculation - well, any calculation -

8   you recognize the lost capacity and the associated

9   costs.

10   Well, I think that is the answer.

11   Q. So, is it fair to say then that while

12   you don't do any specific runs of the F&D model, you do

13   use your judgment to --

14   A. Actually -- I am sorry, I shouldn't

15   interrupt.

16   Q. You do use your judgment to adjust

17   some of the inputs?

18   A. There is another factor. We will

19   use - for instance, when we know there is an effect of

20   one per cent say on a forced outage rate - Mr. Snelson

21   gave you a rule of thumb that allows you to do a quick

22   assessment of the impact and you just do that

23   automatically. You wouldn't do a whole computer run

24   to do that; you can do it in your head and you can work

25   with that.

1   Q.   We were talking about system

2   reliability.   What about the target reserve margin?

3   A.   Well, again, the target reserve

4   margin would be affected, but this would be in the

5   nature of -- I mentioned to you earlier that there are

6   thousands of parameters that attempt to describe the

7   electrical system.   There are millions of parameters

8   that describe it in real life.

9   And at any point in time, those

10   parameters are changing all the time.   And unless there

11   were some -- you sort of don't analyze every time a

12   parameter changes.   You wait for really significant

13   changes or significant groups of changes or some

14   particular study requiring certain information and you

15   would do it then.

16   MR. SNELSON: A.   One of the remarks that

17   Mr. Taborek made in his direct evidence yesterday was

18   that the effect of running into our SO(2) limit is not

19   modelled in our reliability calculation.

20   And the reason for that he explained, is

21   that the reliability calculation is being done to

22   decide how much generation capacity is required on the

23   system.

24

25   ...

1   [11:20 a.m.] If you run into the SO(2) limit, the

2   solution is not to build more generating capacity

3   usually; the solution is usually to add more SO(2)

4   controls to existing generating units. So, that's the

5   reason that in the reliability calculations, the SO(2)

6   limit is not considered to be a constraint.

7   Q. So it's not a constraint, because you

8   are going to do what has to be done to those units to

9   ensure that they meet the limit?

10   MR. TABOREK: A. Yes.

11   MR. SNELSON: A. Yes.

12   MR. TABOREK: A. There is another

13   undercurrent that comes back to some statements that we

14   made earlier, that we have gone through many areas of

15   the model and we have noted areas in which the model is

16   very good and areas in which it has deficiencies.

17   I think one of the things you are seeing

18   from us, that we don't run the model all the time and

19   use the model as our sole basis for decision-making,

20   because we are basically exercising judgments about how

21   much it can be relied on compared with experience,

22   compared with similar calculations, compared to what

23   other people are doing. You seem to be expecting us to

24   run the model more as if everything depends upon the

25   model. It is just one of the tools that we use.

1   In this area of reliability, I have heard

2   people say this, but this area of reliability is one

3   where this is especially true because of the difficulty

4   of modelling this complex situation and these rare

5   events, and I don't mean to demean the model by saying

6   that either.

7   Q. No. It's a tool and you use that in

8   conjunction with your judgment based on your

9   experience, your knowledge of the system, and you come

10   up with a figure that you feel is reasonable.

11   We have been talking about the existing

12   regulations and whether any of the situations described

13   on page 83 of the reliability review can arise. What

14   about the proposed regulations? I assume that if these

15   situations can exist and arise under the existing

16   regulations, even more so can they arise under the

17   proposed regulations.

18   A. Well, this is especially difficult to

19   answer because you are asking for a hypothesis. And   -

20   when you are looking at regulation a word or a comma

21   can cause an enormous difference in how you react. One

22   of the purposes of making a proposal and making it

23   public is to invite comment. It's been my experience

24   that governments have usually taken comments and

25   weighed them in the light of what they wish to achieve

1   and what it costs society to get there, and they

2   usually make some very sensible adjustments. And I act

3   on the basis that that will continue to occur in the

4   future. You have to wait and see. You are not sure.

5   And there is a tendency -- early on, when

6   I opened my discussion, I made some very elementary

7   comments about peak is power in an instant and it has

8   no energy and no emissions, and energy is power over a

9   long period of time and that's where the emissions are.

10   It's very tempting for legislators to

11   say, "There's a coal plant, put a scrubber on her," or

12   "There is a coal plant, do this," without checking to

13   see if it produces any emissions or not. And it's

14   tempting to want to sort of apply blanket rules to some

15   other criteria which doesn't recognize how much

16   emissions or things like that come from plants, and if

17   those kind of laws were to go in place, it would have a

18   serious effect.

19   But I believe, the experience I have had

20   with governments is that they do recognize those

21   effects, that you are getting no gain and enormous

22   cost, and so they do tend to adjust the regulation

23   suitably.

24   Q. What lead time is required between

25   the adoption of a new regulation that would have any of

1   the effects listed above, that's the ones that we have

2   been discussing, and construction of new generation if

3   that was required to mitigate any of the adverse

4   effects on system reliability?

5   A.   Well, the lead times, the lead times

6   that we have put forward for the DSP, are in Chapter

7   15.

8   MR. SNELSON: A.   14.

9   MR. TABOREK: A.   14.   And for our

10   purposes, we have notified that once we have approval,

11   we, on the reliability side, are planning for CTUs for

12   a 4-year lead time, but that those are not

13   energy-producing devices; those are capacity-producing

14   devices for peak.

15   I presume, since you are looking with

16   emissions, you are looking at energy-producing devices

17   and so you are looking at lead times appropriate to

18   base load rather than peak load generation.

19   Q.   If we are interested in the

20   reliability impacts at the moment, should we not be

21   talking about the lead time for, say, a gas turbine?

22   A.   If the problem you are dealing with

23   is a capacity problem, the blip, the hour, et cetera,

24   but if you are saying an environmental regulation has

25   been applied and it's affecting base load plant and

1   that's the problem, then you are looking for base load

2   plant to replace it.

3   Q.   And if that's the situation, you are

4   not talking CTUs, you are not talking a 4-year lead

5   time; you are talking base load units, nuclear or large

6   coal.

7   A.   Yes.

8   Q.   And you are talking considerably

9   longer leads times; is that fair?

10   A.   Yes.

11   MR. SNELSON: A.   Just to correct myself,

12   the lead times are actually given in Figure 15-6 of

13   Exhibit 3 which is chapter 15, not chapter 14.

14   Q.   Thank you, Mr. Snelson.

15   Has Hydro done, or is Hydro planning to

16   do, any analysis to anticipate and prepare for any

17   adverse effects on system reliability resulting from

18   future environmental regulations?

19   MR. TABOREK: A.   Yes.

20   Q.   Can you tell us what they are?

21   A.   What we do is we analyze the

22   regulations that are being proposed and provide

23   comments to the governments that are proposing them in

24   such a fashion that they can achieve their objectives

25   at the least cost as far as they impact on our

1   generation.

2   Q.   Can you tell us two or three of the

3   more important proposed regulations that you are

4   looking at right now?

5   A.   There are proposed regulations

6   developed by the federal and provincial governments

7   working together to control NOX and VOCs, volatile

8   organic compounds.

9   These particular regulations, as they

10   affect NOX, would for generating stations in the

11   Windsor to Quebec corridor, and in Southern British

12   Columbia where there are high NOX levels leading to

13   VOCs, as I understand the chemistry, impose a

14   regulation that what is written in terms of

15   fossil-fueled units - and this a loose translation -

16   shall not exceed -- I am not sure if it's 100 or 200

17   nanograms per joule of heat input, I think. But the

18   specific numbers aren't important.

19   The effect of this is that it is a

20   regulation that would not discriminate between whether

21   a plant was a base load unit producing a lot of

22   emissions or a peak load unit producing little or no

23   emissions, and it would not discriminate between

24   whether this was a brand new plant or a plant in the

25   last year or two of its life.

1   And the effect of the number that's in

2   there is to cause, in effect, a device called selective

3   catalytic reduction to be fitted to control the NOX.

4   Now, regardless of the jargon that

5   describes it, what it is, it's a large capital cost

6   item to remove roughly 80 per cent of the NOX.

7   What we are essentially noting, and this

8   is a point we continually have to note in regulations,

9   that if you put a large capital cost on a unit which

10   produces a lot of output and which has a long life

11   ahead of it, the capital cost is written off over a

12   long period, it can be economic.

13   If, however, you put the same capital

14   cost on a unit that is a peaker, that seldom runs, that

15   produces little in the way of emissions and that has a

16   short life attached to it, to sort of make the extreme

17   case, that plant becomes decidedly uneconomic, and if

18   you were to push that regulation, you can achieve --

19   well, you will basically spend a lot of money removing

20   no emissions, is what it boils down to.

21   MS. RYAN: A. If I could just expand on

22   what Mr. Taborek has said. That is a good example

23   because it's the development of regulation where

24   government has in fact participated in a consultation

25   process with provincial, federal governments, with

1   industrial associations and with environmental interest

2   groups. And the first form of the regulation was in

3   fact a per unit emission per unit of energy type of

4   regulation. And after such discussions that if we want

5   a cost-effective regulation to reduce the most nitric

6   oxide we can for the least amount of money, that there

7   were other options.

8   The consultation process seems to be

9   leading to a regulation that will in fact be an

10   emission cap for an industrial sector or an industry.

11   An they can then decide the most cost-effective way to

12   reduce their emissions.

13   So we are at the process now that we are

14   expecting that we will be expected to reduce our NOX

15   emissions in the future, but we are still at the

16   process of discussing, so we really don't know what the

17   level would be or the timing will be, but certainly, it

18   looks like we will have more flexibility in the options

19   we use to reduce our emissions in the future.

20   MR. TABOREK: A. There are other

21   regulations and they often fall into that very same

22   trap of confusing peak and energy.

23   MR. WATSON: I was going to turn to

24   another sub area, Mr. Chairman.

25   THE CHAIRMAN: Fine.

1   We will take a 15-minute break.

2   THE REGISTRAR: This hearing will recess

3   for 15 minutes.

1   ---On resuming at 11:50 a.m.

2   THE REGISTRAR: Please come to order.

3   This hearing is again in session, please be seated.

4   MR. WATSON: Q. Still dealing with

5   reserve margin, moving to a subarea dealing with

6   emergency actions. Panel, if you could refer to

7   Exhibit 137, page 26A. That is page 84 of Exhibit 87.

8   Excuse me, that is page 26B, Table 6.3, the next page.

9   THE CHAIRMAN: That is 103 of 87?

10   MR. WATSON: Yes.

11   Q. This table shows that there are 2500

12   megawatts of emergency measures available. That

13   includes 200 megawatts of general public appeal and 200

14   megawatts of limited industrial appeal. The next page

15   of that exhibit is page 105, and near the top that...

16   THE CHAIRMAN: Which is again 87 is it?

17   MR. WATSON: Yes, that is page 105,

18   Exhibit 87.

19   Q. At the top of that page, that says:

20   "About 1,000 megawatts of different

21   types of public appeals are available."

22   Panel, could you help us out as to the

23   correlation between the 1,000 megawatts of public

24   appeals that are mentioned on page 105, and the 400

25   megawatts of appeals that are mentioned on page 103?

1   MR. TABOREK: A. Just give me a second,

2   please.

3   Q. Certainly.

4   A. There is either of two possibilities.

5   While you see on Table 6.3, page 26B, 200 and 200

6   megawatts totaling 400, which is roughly 2 per cent of

7   the load or 2 per cent of the margin, you will see on

8   page 28 an expansion in Table 4.7.

9   THE CHAIRMAN: Page 28, of what document?

10   MR. TABOREK: That is the same exhibit,

11   it is just a few pages on.

12   THE CHAIRMAN: So, that is page 98 of 87.

13   MR. TABOREK: 79.

14   THE CHAIRMAN: Oh, sorry, 79.

15   MR. TABOREK: The written number is 28,

16   and the printed number is 79.

17   MR. WATSON: Q. That is Table 4.7?

18   MR. TABOREK: A. The first two, the

19   general public appeal and the limited industrial appeal   -

20   are here in percentage terms, but that is your 200 and

21   200 megawatts.

22   Q. Those figures are roughly equivalent,

23   that is what you're saying?

24   A. Yes.

25   Q. One per cent for each of those

1   corresponds roughly to 200 megawatts?

2   A.   To 200 megawatts, yes.   Then the full

3   industrial appeal would add another three per cent.

4   So, option 1 is that the 1,000, I think, corresponds to

5   a full five per cent, and that 1,000 may refer to that.

6   Now, if that is the case, there is

7   another option. Possibly it is a typo, because this is

8   written really talking about the 400, and so I think we

9   should put 400 on that page instead of 1,000. So I'm

10   not sure of the exact reason, but the -- no, this -- it

11   should have 400 to be read properly.

12   Q.   Well...

13   A.   Because it is about that table, and

14   it is not about the larger one.

15   Q.   Isn't there a third option? Isn't

16   the third option that if you look at Table 4.7, which

17   gives 5 percentage points of appeals, then you refer to

18   page 105, which talks about the 1,000 megawatts, which

19   would seem to correspond to Table 4.7.

20   A.   Okay.

21   Q.   Then wouldn't the third option be

22   that Table 6.3 should be increased by 600 megawatts?

23   A.   No, no, definitely not.

24   Q.   That is not a third option.

25   A.   No, that is not a third option,

1   because...

2   Q. Why wouldn't that logic flow, that I

3   just went through, apply?

4   A. If you go back to Table 4.7 again,

5   you will note the text that follows it says, in effect,

6   that the full industrial appeal is, in effect, a load

7   cut, and that it is not without cost and hence should

8   not be included in the category of appeals with little

9   or no cost.

10   THE CHAIRMAN: Where are you reading that

11   from?

12   MR. TABOREK: Again on page 28,

13   written -- it is below Table 4.7, and it is the

14   paragraph below, where it describes the different types

15   of appeals. And the paragraph is in effect saying that

16   we will only consider the first two types as emergency

17   measures without cost, because the third type is, in

18   effect, a load cut with notice, I think is the term.

19   And that it does have a cost associated with it.

20   So it is properly categorized as a load

21   cut, and not a little or no cost emergency measure.

22   MR. WATSON: Q. Well, if...

23   MR. TABOREK: A. So I think the easiest

24   thing, looking at this, is just change that 1,000 to

25   400, and it will read smoothly and continuously. Maybe

1   that is a slip of the author, a typo, I'm not sure

2   what.

3   Q.   Just so I understand then, the full

4   industrial appeal, while it is called an appeal, is in

5   effect, an outage.

6   A.   Yes.   The term a full industrial

7   appeal amounts to a blackout with notice is the phrase

8   used.

9   Q.   So it is an outage, and, as such, it

10   is therefore not an emergency measure.

11   A.   Correct, yes.   That is the flow of

12   this argument here.

13   MR. SNELSON: A.   It is not an emergency

14   measure with little cost.

15   MR. TABOREK: A.   With no cost.

16   Q.   We are going to get into some figures

17   a little later on about the cost of outages.   One of

18   the figures that you are certainly aware of, and the

19   Board will become aware of as we go through this, is a

20   figure of $5.91 as an outage cost, if you will.

21   Does that outage cost apply to this

22   particular outage that we are talking about, which is

23   the full industrial appeal?

24   A.   Yes.

25   Q.   Well, could we leave this in this

1   fashion? As I understand it, what you are saying is

2   the figure of 1,000 on page 105 should be 400.

3   A. Yes.

4   Q. Could you check with the author of

5   that figure to determine if, in fact, that is a typo,

6   as you thought, or whether he or she had some rationale

7   or she had some rationale for that 1,000 megawatt

8   figure, and there is some explanation for that

9   correlation or the noncorrelation to that?

10   A. I can answer you right now, the

11   1,000 -- let's see, 103, 105; 104 is missing. Okay,

12   yes, I will do that. I will check through what is on

13   104 and get back to you.

14   Q. Thank you.

15   I understand that both voltage reductions

16   and public appeals are included in the calculation of

17   system minutes? That is correct?

18   A. Yes.

19   Q. The demand reductions through public

20   appeals and voltage reductions are assumed to have no

21   cost?

22   A. Yes.

23   Q. That is contrasted with rotating

24   outages, which do have a cost?

25   A. Yes.

1   Q.   Now were these two emergency actions,

2   that is the appeals and the voltage reductions, in fact

3   modelled as having no cost when you were setting the

4   target reserve margin?

5   A.   Yes.

6   Q.   That was in Exhibit 87, which is the

7   '91 reliability review. Does the same answer apply for

8   the earlier reliability analysis you were doing with

9   respect to the DSP?

10   A.   There were -- oh...

11   MR. SNELSON: A. The answer with respect

12   to what is costed is the same, I believe. That

13   rotating load cuts are costed and voltage reductions

14   and public appeals have no costs attributed to them.

15   In the 1981 report, as to what was

16   counted in the system minutes that were reported, then

17   the rotating load cuts and the public appeals were

18   counted. There were also some differences in the

19   modelling of operating reserve and hydraulic, where

20   they fit into the order in which things are done. So

21   there are a number of differences in the way in which

22   things are counted. But the same things were costed.

23   Q.   It has been consistent throughout?

24   A.   I believe so.

25   Q.   Were you going to add something, Mr.

1   Taborek?

2   MR. TABOREK: A.   No.   I think what I was

3   going to add is that the work done in the early stages

4   of DSP used the 25 system minutes, which was the 1981

5   work, and that sort of ties in with what Ken has said.

6   Q.   Panel, if you could turn back to page

7   11 of Exhibit 137, which is Table 2 from the 1981

8   reliability review, and I'm going to focus on appeals

9   for these series of questions.

10   One very quick question of clarification

11   before we start. In my copy, and the copy that my

12   client received, we had great difficulty in reading the

13   value of rotating load cuts under unsupplied energy in

14   average with uncertainty.

15   A.   I think that is just meant to be a

16   star rather than a numeral. I will just check with my

17   copy to see if...

18   MR. SNELSON: A.   It has to be a star.

19   MR. TABOREK: A.   Yes, it is a star.

20   rather than a numeral.

21   Q.   That means it is very...

22   A.   The value is very small.

23   Q.   I notice in the table, there are

24   other values which are less than one.

25   A.   Yes.

1   Q.   So, when you say small?

2   A.   It is much less than -- near zero.

3   What it is indicating is that -- the model is

4   interestingly pointing out that, with the kinds of

5   values the public puts on customer damage cost, they

6   will tolerate only very small amounts of load cuts, and

7   that most of the system minutes that we can acceptably

8   put into our calculation is in effect system minutes of

9   unsupplied energy with no cost, i.e., the appeals.

10   Q.   This table, and as you pointed out

11   yesterday, this is an '81 table done on '81 data, this

12   table shows a much larger quantity for unsupplied

13   energy due to appeals versus unsupplied energy due to

14   rotating load cuts.

15   A.   Yes.

16   Q.   Now that is in 1981, using the '81

17   data. Now talking about today, and in fairness to you,

18   you have indicated that appeals are reduced from ten

19   per cent to two per cent. But even taking both those

20   factors into account, don't we have a situation where

21   appeals -- don't we have a situation where the unserved

22   energy from appeals is still very much larger than the

23   unserved energy from outages?

24

25   ...

1   [12:05 p.m.] A. From load cuts, yes. And in effect,

2   if you are looking at that same column and you were

3   doing it now, you may have something about one or so.

4   If you were recording the results of the latest

5   calculations that we have reported in Exhibit 86 in a

6   tabular form such as this --

7   Q. You said 86?

8   A. Eighty-seven, I am sorry, 87, the

9   star would become a small number like one or two and

10   the 15 to 35 range would become become a number -- oh,

11   so that the total was around 10.

12   Q. So, about an order of magnitude, ten

13   to one?

14   A. What is the order of magnitude now?

15   Q. The difference between the two.

16   A. Well, you are asking about public

17   appeals and I was saying the 15 to 35 would now be

18   something a little less than 10.

19   Q. Yes. And the rotating load cuts

20   would be about one?

21   A. Yes, compared to being near

22   negligible to being roughly one or two.

23   Q. So, there is about an order of

24   magnitude difference between the rotating load cuts and

25   the appeals?

1   A.   Yes.

2   Q.   Now, why didn't Hydro include the

3   cost to customers of appeals?

4   A.   Because the assumption was that there

5   was no cost to customers of appeals. Another way of

6   saying it is that it is so small as to be negligible.

7   Q.   Okay. Why did you assume --

8   A.   That, in effect, determines the

9   percentage that you believe you can get because it is

10   at little or no cost.

11   Q.   Well, that is your assumption that it

12   is at little or no cost?

13   A.   Correct.

14   Q.   Now, where does that assumption come

15   from?

16   MR. SNELSON: A. It was a judgment and

17   it was based on the view that if you made appeals, then

18   most of the uses that will be cut back as a result of

19   appeals are quite discretionary things. So, perhaps

20   somebody will be a little bit more careful about going

21   around their house because there is an appeal on the

22   radio and turn off the light in the room they are not

23   using. They probably won't turn off the light in the

24   room they are using.

25   MR. TABOREK: A. And the two per cent

1   number that we use now, for instance, is a result of

2   having made some appeals and attempting to measure the

3   difference that the appeals made, and this is a

4   difficult assessment to make because it is difficult to

5   keep all things equal. But there was a judgment that

6   we got about one per cent in a public appeal as a

7   reasonable number. It is probably a bit high, but a

8   workable number. And the logic was that when people do

9   cut back in that instance, there is little cost

10   associated with it.

11   And then, as you have said, the similar

12   limited industrial would give a similar. So that was

13   the chain of logic that lead us to the two per cent at

14   no cost. Little cost, I think, is better to say.

15   Q. No cost, not little?

16   A. Little cost, I think, is -- little or

17   no cost.

18   MR. SNELSON: A. No cost is modelled.

19   MR. TABOREK: A. Yes.

20   MR. SNELSON: A. The judgment is little

21   cost.

22   Q. We will be dealing later, in a few

23   minutes, with the surveys that were conducted with

24   respect to to determining the customer outage cost

25   which amount to, I believe it was, the 5.91 figure that

1   I talked about earlier.

2   Were any surveys or any other types of

3   analysis done with respect to the cost to customers of

4   appeals, or is this just a pure judgment as you have

5   indicated?

6   MR. TABOREK: A.   I have described to you

7   what happened.

8   Q.   No surveys?

9   A.   No surveys.

10   Q.   Okay.   I understand that other

11   utilities have estimated the cost to customers of

12   demand reductions in response to appeals.

13   Has Hydro made any such estimates?

14   A.   Not that I am aware of.

15   Q.   Mr. Snelson, you have mentioned that

16   while its model is zero, the word you used was

17   "little."

18   MR. SNELSON: A.   The judgment is that it

19   is little or low cost.   We don't know what the cost is

20   and we model zero.

21   Q.   Okay.   Have you estimated the impact

22   on the target reserve margin of including costs from

23   appeals?

24   MR. TABOREK: A.   Some assistance

25   perhaps, not in the way that you have described it, but

1   something that will assist you in that regard is that

2   in Exhibit 87, the sensitivity of doubling or having

3   the customer damage cost of $5.91 -- call it $6.00 --

4   it doesn't deserve to be that precise -- was looked at

5   and the percentages, if I can find them -- excuse me

6   for a second.

7   Q.   That is page 96 of the reliability

8   review.

9   A.   Yes.   And what I am proposing is that

10   while there is more in the way of public appeals than

11   there is in the unsupplied energy in public appeals

12   than there is in rotating load cuts, if you allocated

13   some lower rate, such that it ends up doubling your

14   total or halving your total, you can then use these

15   charts to get a feeling for what it would be.

16   And roughly, you will notice -- the

17   comparisons to make is if you take the first line, say

18   the monthly storage Hydro line, you -- oh, and be sure

19   to use the corrected value of figure 5.1, which I am

20   not.   There was an errata filed on figure 5.1.

21   So that the first line, "monthly Hydro

22   storage" --

23   Q.   Mr. Taborek, could I just interrupt?

24   You are now on page 97, Table 5.1?

25   A.   Yes.   And I think the material you

1   handed out did not have the errata in it, so maybe I

2   should correct that.

3   THE CHAIRMAN: I have it here. I don't

4   know whether anybody else has it.

5   MR. TABOREK: A new Table 5 .1?

6   THE CHAIRMAN: The new Table 5.1, yes.

7   MR. TABOREK: And the first line,

8   "Monthly Hydro Storage" should be 20 to 22 per cent?

9   THE CHAIRMAN: Yes.

10   MR. TABOREK: Okay. Good.

11   Then what you would do is you would

12   compare that line with the second last line, and it

13   would say that if your customer damage costs were

14   halved for whatever reason, you would reduce the

15   reserve margin that gave you minimum total customer

16   costs by somewhere from one to two per cent; and then

17   comparing the first line with the last line.

18   If you were to double the customer damage

19   cost, you would raise your reserve margin from minimum

20   total customer cost by about one per cent, so you could

21   get a feeling for that.

22   MR. WATSON: Q. If we could turn back to

23   Table 2. Again, that is page 11 of Exhibit 137. We

24   have been talking about appeals. I would like to turn

25   now to voltage reductions.

1   And you will notice under the frequency

2   and duration columns, there are values given for

3   voltage reduction; and those values are larger than the

4   values for public appeals and for rotating load cuts.

5   No value is given for voltage reduction

6   in the unsupplied energy column; however, would it be

7   fair to say that, if numbers were supplied, they would

8   be larger than the appeal numbers in the same way that

9   the frequency and duration numbers are larger?

10   MR. TABOREK: A. I think the answer is

11   yes. And there may be a way to -- if you look at

12   figure 2.3 of the 1981 reliability report, which is

13   Exhibit 140, and the figures at the back of the

14   report -- oh, I am sorry, that is giving frequency; it

15   is not giving unsupplied energy with respect to that.

16   No, I am sorry, I am misleading you.

17   Let me rest with a "yes." I thought I

18   might be able to give you some numerical development of

19   it, but I can't.

20   Q. Okay. So, it would be bigger.

21   Earlier when you were talking about the

22   difference between appeals and load cuts, we were

23   talking roughly an order of magnitude from one for the

24   rotating load cuts up to around ten for the appeals.

25   Voltage reduction is going to be larger.

1   Is an order of magnitude larger again?

2   MR. SNELSON: A. I think we need a

3   caution here, and that is that these load cuts are

4   actions in Table 2 are shown in a specific order. The

5   assumption in coming to this table was that as you get

6   progressively into trouble, you would cut managed

7   loads, which is on the top of the table, which in our

8   current terminology is load shifting. That is move

9   loads.

10   You would then cut interruptible loads.

11   You would then call upon the interconnections for

12   emergency assistance. You then reduce voltage and so

13   on down the table in that order.

14   THE CHAIRMAN: What does the next one

15   stand for? I can't read it.

16   MR. SNELSON: BHWP.

17   THE CHAIRMAN: What is that?

18   MR. SNELSON: Bruce Heavy Water Plant.

19   And that action is the cutting of the electrical load

20   to our own heavy water plant, which we treat as

21   something like an interruptible load. We would stop

22   making heavy water in a capacity emergency. This

23   particular order of actions has a certain degree of

24   uncertainty to it.

25   And Mr. Barrie on my right would explain

1   from an operating perspective that the order in which

2   these actions take place is not necessarily the order

3   which is shown here. For instance, it may be that

4   public appeals would be made in anticipation of a

5   problem which may or may not occur. And that the need

6   for voltage reductions might be held in reserve as

7   something to do at a later time when the problem

8   occurs. Now, if the problem doesn't actually occur,

9   you have made the public appeals first.

10   And so, the ratios of these numbers does

11   depend upon the order in which these actions are taken.

12   Clearly, all of the actions will be taken before we

13   start to cut firm load. Cutting firm load is the last

14   thing that happens. But the order in which these

15   emergency measures take place -- for convenience of

16   modelling, we have to assume an order, but in reality,

17   the order may be different, and that would affect the

18   ratios between these various quantities.

19   But the principle you are driving towards

20   is correct, that the unsupplied energy from voltage

21   reductions will be considerably higher than that

22   associated with firm load cuts for a reasonably

23   reliable system.

24   A system that is designed to be

25   reasonably reliable will have a larger proportion of

1   unsupplied energy associated with public appeals and

2   with voltage reductions than with rotating load cuts

3   because if you have achieved a reliable system, you

4   have very small limited rotating load cuts.

5   MR. WATSON: Q. It is going to be

6   larger --

7   THE CHAIRMAN: I don't think you still

8   got the answer to the question you asked.

9   MR. WATSON: The question was--

10   THE CHAIRMAN: Which was, what is the --

11   MR. WATSON: Q. --is it going to be an

12   order of magnitude larger in the same way that the

13   first two differ by an order of magnitude? Is that a

14   fair estimate or is there another estimate which would

15   be a little closer?

16   MR. TABOREK: A. An order of magnitude

17   larger than the star -- oh, than the appeals?

18   Q. Yes.

19   MR. SNELSON: A. No, I would estimate it

20   to be of the same order of the appeals, but when I say

21   an order of magnitude, I am thinking of a factor of

22   ten.

23

24

25   ...

1   [12:20 p.m.] Q. That's what I am talking about.

2   A. There are different interpretations

3   of what is an order of magnitude.

4   Q. Okay, perhaps I should clear that up

5   then. My definition of an order of magnitude is a

6   factor of 10. That's why I indicated that there was an

7   order of magnitude difference between rotating load

8   cuts at one and appeals at 10.

9   A. Yes.

10   Q. So, you are saying it would not be an

11   order of magnitude using that definition up to voltage

12   reductions but it is some larger value. Twice as

13   large?

14   A. You could use the model to estimate

15   the size of the unsupplied energy, but I am not sure

16   that I would attribute very much significance to the

17   results, because the result depends upon the order in

18   which these emergency measures are undertaken and any

19   order that you put into the model is to some degree   -

20   arbitrary. It depends on the characteristics of the

21   particular situation, how quickly the problem develops,

22   how much of it is foreseen by the operators and what

23   actions they take to reduce it.

24   So, that it is larger than rotating load

25   cuts is plain, not that far different perhaps from

1   public appeals but we don't really have a good

2   estimate.

3   MR. BARRIE: A.   I wonder if it would

4   help if you looked at an actual year where this

5   actually occurred.   It may not be exactly relevant to

6   the future 20 years, but it certainly gives an

7   indication of orders of magnitude at least.

8   We don't do these very often, first of

9   all, so you have to pick 1989, probably, when we did

10 have voluntary curtailment, or public appeals, if you

11 will, and we had voltage reductions.   It's actually in,

12 reported in Exhibit 138.

13   THE CHAIRMAN: Am I right, you once

14 described it as a bad year; is that right?

15   MR. BARRIE: Bad year.

16   Would that be beneficial, to look at an

17 actual year?   It's the only year we have where we can

18 make this comparison.

19   MR. WATSON: Q.   It's the only year you

20 have and it's a bad year?

21   MR. BARRIE: A.   Well, when it's not a

22 bad year, we don't do this.

23   Q.   Could you just tell us the figure?

24   A.   I can quickly tell you the figure.

25 In 1989 voltage reductions were carried out and they

1   resulted in 89.3 system minutes. The same year, and

2   almost over the same periods, public appeals resulted

3   in 20.5 system minutes. That's from Exhibit 138, the

4   1989 performance reliability report. I should add that

5   what was --

6   THE CHAIRMAN: What about load cuts?

7   MR. BARRIE: Zero load cuts.

8   THE CHAIRMAN: Zero. Did the public

9   appeals include industrial appeals?

10   MR. BARRIE: Limited industrial appeal,

11   as Mr. Taborek --

12   THE CHAIRMAN: Included limited

13   industrial appeals?

14   MR. BARRIE: Yes, sir.

15   But I think I should emphasize, that is

16   always an estimate. We do not do trials for public

17   appeals. So what we have to do is we have to look at

18   the demand curve after the fact and estimate what it

19   would have been had there not been a public appeal. So

20   as such, there is an element of a good deal of

21   judgment.

22   In the case of voltage reductions, it's

23   the same, except in that case we do do tests. We do

24   tests twice a year, so we have a better feel. We feel

25   for comfortable about the estimate we gave for voltage

1   reductions than we do for public appeals.

2   MR. WATSON: Q. And your estimate for

3   voltage reduction is that it is larger than public

4   appeals?

5   MR. BARRIE: A. Yes, it was

6   approximately -- well, it was 89 compared to 20.

7   Q. Well, in fairness to you, you said

8   that was a bad year. In a good year you are still

9   going to have your voltage reduction larger than your

10   public appeal, are you not?

11   MR. TABOREK: A. In a good year, you can

12   have either.

13   MR. BARRIE: A. You can have either.

14   I should refer you to the diagram. If

15   you want to pull it out, figure 2.14 in Exhibit 138,

16   and it is very, very evident we had -- well, I can just

17   read the numbers off. We had 89, as I said, in 1989;

18   we had three in 1988 and one in 1985, and none in all

19   the other years. So I am giving you the year that we

20   have some data to give you.

21   Q. Sure.

22   MR. TABOREK: A. One of the things that

23   I think is happening here is when we talk reliability,

24   we tend to talk about averages and expectations, which

25   are, in effect, averages over a period of time, and

1   what they tend to do is to mask the reality.

2   Generation planning is a game of odds.

3   Q. Sorry?

4   A. It is a good of odds, probabilities.

5   You do not get the average amount of outages in every

6   year. The way it's set up, that you will go on for

7   many, many years with no problems, and then you will

8   get a year with problems, '89. And when add that big

9   problem year in with a bunch of no problems years you,

10   in effect, get an average.

11   I have a rather morbid analogy. It's

12   like Russian roulette. The fact that some people click

13   on an empty chamber is not an indication that this is

14   something that it's wise to do. What you are very much

15   concerned about is that one bad year, if you will.

16   The reliability game is like this, and

17   the interesting thing about it is you can do some very

18   foolish things on the generation reliability side and

19   you can be lucky and you have no problems. Now, the

20   obverse, you can do some very clever things and you can

21   be unlucky and you can have problems.

22   It's because generation reliability is

23   like that that we do these expectations and we look

24   very much at the case of, how close are we to this

25   problem area? You don't want to position yourself

1   right on it because the nearest variation is going to

2   put you into a really serious problem. And so that's

3   one of the difficulties in dealing with averages and

4   numbers.

5   MR. SNELSON: A. That is why Table 2--

6   MR. TABOREK: A. Was done.

7   MR. SNELSON: A. --of the 1981 report,

8   which was page 11, I believe, of your Exhibit 137,

9   that's why page 2 was structured the way it is. And

10   you notice that each estimate has three columns, an

11   average width uncertainty which is the mathematical

12   expectation of taking all the possible outcomes and

13   weighting them by their probabilities to give an

14   expected value; an average with no uncertainty which is

15   the most likely thing that's going to happen, and the

16   bad year which was chosen to be about a worst case in

17   10 chances, that is the way it was defined.

18   Basically, most of the average width

19   uncertainty comes from the something similar to the bad

20   year, the worst in 10 years. So, it's a few bad years

21   that drive reliability, as Mr. Taborek says. And we

22   particularly structured this table to show that it was

23   the bad year that was the main driver and that that's

24   really the problem that we are addressing, how do you

25   stay away from these bad years once in a while.

1   We may have been lucky in 1989 in that we

2   had one bad year. There is a tendency, once you get

3   into a problem with generation planning, for it to take

4   you a while to get out of your problem. And so bad

5   years can actually cluster together. If there is a

6   one-in-ten chance of their being a bad year, then if

7   you were in a bad year this year, there is a much

8   higher than one-in-ten chance that you will be in a bad

9   year next year, because if the answer, say, is to build

10   new generation, that's going to take four years,

11   perhaps longer.

12   Q. Panel, if you could turn to page 30A

13   of Exhibit 137, which is Table 6.4 of Exhibit 87.

14   THE CHAIRMAN: I'm sorry?

15   MR. WATSON: That's page 30A of Exhibit

16   137. It's page 104 of Exhibit 87.

17   THE CHAIRMAN: Thank you.

18   MR. WATSON: Q. I am still dealing with

19   voltage reduction. Table 6.4 shows a sample of

20   problems reported with voltage reduction in the year

21   1989. And, Panel, as you go down that table you will

22   see that there are six items. It lists some of the

23   difficulties that occurred as a result of voltage

24   reduction and it actually refers to equipment damage

25   that resulted. So we are dealing here not only with

1   inconvenience but actual customer damage as a result of

2   voltage regulation; is that not correct?

3   MR. TABOREK: A. Yes.

4   Q. As actual damage is ocurring, has

5   Hydro estimated the cost to customers of these voltage

6   reductions?

7   A. No.

8   MR. SNELSON: A. I think the point here

9   is that the 3 per cent voltage cut is done from time to

10   time.

11   THE CHAIRMAN: Just a moment. I think

12   the question was, have they estimated the cost? Wasn't

13   that the question?

14   MR. WATSON: Yes. In fairness, they

15   answered that question, they said they had not.

16   THE CHAIRMAN: They had not. I'm sorry,

17   I missed that.

18   MR. SNELSON: But there is a response to

19   the equipment damage, and that is that, if you note,

20   that the areas where damage is known to have occurred

21   are excluded from future voltage reduction tests.

22   MR. TABOREK: And I would like to

23   elaborate on the word "estimate," because I am sensing

24   when you speak to me, you are looking for a study

25   that's in a book that has computer programs run and

1   this kind of thing, and no, we have not done that.

2   What you are seeing here, when we do a

3   review like this, one of the things we do is call into

4   question all of our assumptions, and our assumptions

5   usually are never absolutely true in every conceivable

6   case. They are the most appropriate for the

7   circumstance to be able to model it. Now, this list of

8   cuts is actually an extract of a shorter list that I

9   felt was a bit too long to put in the report.

10   If you look at these, while there is some

11   damage occurring, that it is on a relatively small

12   block of megawatts. And, as Ken pointed out, we are

13   basically reacting to that by not affecting the voltage

14   reductions in those areas.

15   And having said that, so that in the case

16   of the review, we are, in effect, pointing out that

17   these voltage reductions are not totally with no cost,

18   but even having noted this, that it is still

19   appropriate to attribute to the voltage reductions in

20   this little or no cost.

21   MR. WATSON: Q. I would like to follow

22   up on what you and Mr. Snelson were saying about future

23   voltage reductions. If I understand it correctly, you

24   are saying that through your past experience you find

25   out where the difficulties were, where the damage

1   occurred, and you exempt those areas in the future; is

2   that fair?

3   MR. BARRIE: A.   As operations we will

4   exempt them from any further 3 per cent voltage.   I

5   presume you do.

6   Q.   And I was looking at this table, I

7   notice the very first item is on December 14th, the

8   North Bay Hospital was unable to use their X-ray

9   machine due to voltage cuts and as a result they were

10   exempted.

11   I don't know very much about X-ray

12   machines, but if North Bay Hospital couldn't use their

13   X-ray machine, would this mean that perhaps other X-ray

14   machines could be affected?   And if in fact that's the

15   situation, doesn't an exemption really not make sense

16   in that sort of area?

17   MR. TABOREK: A.   Well, you have made a

18   hypothesis that we cannot verify, and if you make that

19   hypothesis, you can go to your answer, but we can't say

20   one way or the other.

21   MR. BARRIE: A.   Let me answer, in

22   general.

23   The voltages all over the province.   So

24   when we reduce by 3 per cent in a particular place, it

25   doesn't mean that the absolute voltage at that point

1   will be the same if you did the same thing somewhere

2   else. So, the voltage in Toronto will be different to

3   the voltage in North Bay when we carry out a 3 per cent

4   voltage reduction.

5   MR. SNELSON: A. It also varies where

6   you are on a particular feeder from a transformer

7   station. If you are the last customer on the feeder

8   without a voltage reduction, your voltage may be at the

9   lower end of the acceptable band, and a 3 per cent

10   voltage reduction may now bring you to an acceptable

11   level of voltage for your particular equipment.

12   If you are near the sending end of the

13   feeder where your voltage is likely to be towards the

14   high end of acceptable band before the voltage

15   reduction, then the voltage reduction may just bring it

16   down into the middle of the acceptable band.

17   So, there is a wide rage of possible effects that can

18   take place here.

19   Q. As you say, there are a wide range of

20   possible effects that could take place and some of

21   those could amount to further complaints such as the

22   ones that are illustrated here. Everything ranging

23   from equipment that can't be used, to actual damage

24   that could occur.

25   ...

1   [12:35 p.m.] A. I would presume that a hospital that

2   was unable to use its equipment because of low voltage

3   during one of our either low voltage tests or actual

4   low voltage circumstances, would let us know they were

5   having an unacceptable electricity supply.

6   Q. So, the essence of this is you do not

7   include the cost to customers of voltage reductions,

8   you do not have an estimate of what those costs would

9   be, in any event.

10   When we were talking about appeals

11   earlier, Mr. Snelson, you said that while the model is

12   zero, there is some little value associated with them.

13   A. Clearly, to say that they are zero,

14   value zero cost is probably not correct. But we have

15   no means of estimating, and we expect it to be small.

16   Q. And, Mr. Taborek, if I could just

17   wrap this up by saying, in order to determine the

18   effect on the reserve margin, you'd go back to page 96,

19   where you are talking about the effect of a higher or a

20   lower customer damage cost, and that sentence, where

21   you said:

22   "Doubling the customer damage costs

23   would increase the optimum target reserve

24   by about one per cent. Having the

25   customer damage cost would reduce the

1   target reserve by about two per cent."

2   That is the...

3   MR. TABOREK: A. I think that would be a

4 good first cut, yes.

5   Q.   Thank you. If you could look at

6 page 29 of Exhibit 137.

7   THE CHAIRMAN: This is all from 87, is

8 it?

9   MR. WATSON: Yes, that is Table 4.10 from

10 Exhibit 87. It is titled "Key Assumptions in Analysis

11 Using F&D Model."

12   Q. If I could refer you to assumption

13 No. 7, "Duration of Rotating Load Cuts," and you have

14 an assumption of one hour. Where does that assumption

15 come from?

16   MR. BARRIE: A. When putting our plans

17 together of how we will handle a deficiency, we put

18 together a schedule of rotating load cuts. Now we can

19 vary this to whatever we deem to be appropriate.

20   We use this one hour to mean that we will

21 disconnect the customer for one hour, we will restore

22 him and take someone else off. So, that is the one

23 hour reference. It could be changed to something else.

24 This is what is used.

25   Q. And that assumption is represented,

1   that one hour assumption is represented in the F&D

2   model?

3   A.   Yes.

4   MR. TABOREK: A.   Let's see.   No, it is

5   not in the F&D model?

6   MR. SNELSON: A.   The way it works is

7   that the frequency and duration that are reported in

8   the F&D model are the frequency and duration of an

9   incident on the system.

10   So, for instance, there may be a system

11   duration of a problem of three hours.   The assumption

12   is that operations will respond to that by three

13   separate one-hour load cuts to different blocks of

14   customers.   Where it affects the calculation is that

15   the estimate of the cost of unserved energy, of the

16   interruption cost, depends upon the duration of the

17   interruption.

18   So, we have selected to use the cost of

19   interruptions that relates to a one-hour interruption,

20   on the assumption that however many one-hour

21   interruptions are necessary to reduce the problem on

22   the system will be made, and will be made to different

23   categories of customers, different groups of customers

24   in some sort of rotational order.

25   MR. TABOREK: A.   If you were to reduce

1   that duration to about 15 minutes, for instance, you

2   would approximately double the $6 per kilowatthour to

3      $10 or $12 per kilowatthour.

4   Q. So, if you reduce the time assumption

5   by a factor of four, that results in a doubling of the

6   customer cost?

7   A. Yes.

8   Q. Is that a linear relationship?

9   MR. SNELSON: A. No, the relationship,

10   as it was estimated at the time of the system expansion

11   program reassessment studies, which is a SEPRA for

12   short, and I was looking for it in the 1981 report, and

13   I don't see the figure. I believe, or it may be there,

14   but either in that report or in the SEPRA studies that

15   back it up, which have also been given in answer to

16   interrogatories, there is actually a plot of the

17   interruption cost as a function of duration.

18   The SEPRA studies were given in response

19   to Interrogatory 2.7.80, and that is a very large

20   amount of material. I think you will find it in the

21   interim report on reliability. I can't tell you the

22   number of that. It may be the fifth interim report,

23   but that is about -- I can't recall numbers that far

24   back.

25   Q. How does the F&D model account for

1   the need to maintain operating reserves?

2   A.   The assumption is that by the time we

3   actually get to cutting firm load, we will have allowed

4   the operating reserve to go to zero. That is an

5   extreme measure which our operations colleagues try

6   very hard to avoid. But the assumption is that by the

7   time you are into rotating load cuts, then the

8   operating reserve has gone to zero and you are living

9   strictly hand-to-mouth.

10   MR. BARRIE: A.   In actual fact, that is

11   very close to what would happen. Our assumption is

12   that we would go down to just sufficient reserve to be

13   able to regulate the tie lines within some band, which

14   amounts to something like 70 to 100 megawatts, so it is

15   almost zero.

16   Q.   70 to 100 megawatts?

17   A.   Something like that, yes.

18   Q.   So that is below your synchronized

19   reserve margin of 240 megawatts?

20   A.   Yes. This is in this extreme

21   circumstance, where we have exhausted every other

22   measure at our disposal.

23   Q.   So, in effect, what you are talking

24   about is, your threshold is 70 to 100 megawatts, you

25   are less that one per cent.

1   A. Yes.

2   Q. If I could take you back to what Mr.

3   Taborek was saying a little earlier, about walking on

4   the edge of the cliff...

5   A. We are pretty close to the edge

6   there.

7   MR. TABOREK: A. This is.

8   MR. SNELSON: A. But rotating load cuts,

9   in our view, is over the edge; something we try to

10   avoid.

11   Q. Just so I understand, what we are

12   talking about here is the threshold for outages, is

13   that correct? Is there a different threshold for

14   emergency actions?

15   A. This is the very last thing we will

16   do before we interrupt customers. We have done

17   everything else that was on that list. We have

18   appealed for help, emergency help from our neighbors,

19   we have had public appeals, we have voltage reductions,

20   we have done all of those things, then we will cut into

21   our operating reserve and only then. Because the last

22   thing we want to do is interrupt customers.

23   Q. And when do you start the emergency

24   actions, at what operating margin?

25   A. Now, what my colleagues defined as

1   emergency actions in the planning horizon would not

2   necessarily -- I would maybe not define them as such.

3   So, I will have to define what I call emergency

4   actions.

5   If I negotiate extra interconnection

6   assistance over and above the 700 megawatts that they

7   assume, I would not regard that as emergency. That is

8   normal operating practice.

9   Q. Why don't you define what you would

10   look at as emergency actions, and where your threshold

11   would be. If either Mr. Snelson or Mr. Taborek have

12   anything different to add, I'm sure they will.

13   A. I think a simple way to put it would

14   be in that report that I just quoted, the PS&E

15   reliability report, if unsupplied energy is being

16   caused by the action, that would be an emergency

17   action. So, I would call voltage reductions, public

18   appeals, that is the kind of thing I would refer to as

19   an emergency action.

20   Q. What is your threshold for that?

21   A. I'm not sure I understand what you

22   mean when you say...

23   Q. Where do you start that?

24   A. Where do we start that? When we

25   start cut -- if, without doing that, we were to cut

1   into operating reserve, we would do that. We would

2   issue a public appeal, we would do voltage reductions.

3   Q. Where do those actions occur in

4   respect to the 240 megawatt synchronized reserve

5   requirement?

6   A. We would do those actions before we

7   cut into the synchronized reserve.

8   Q. So that would be above that margin?

9   A. Yes.

10   Q. And then you would cut into your

11   reserve margin, and then you are down to that 70 to 100

12   megawatt level that you were discussing earlier?

13   A. Yes.

14   Q. Mr. Snelson, Mr. Taborek, do you have

15   anything to add to that from your planning perspective,

16   as opposed to Mr. Barrie's operating perspective?

17   A. This is the sort of order in which,

18   as I was discussing earlier, the order does not

19   necessarily occur in the order in which it is shown in

20   table 2 of -- which is on page 11 of Exhibit 137.

21   And it is because of the ways in which

22   these things can arise, and while Mr. Barrie has given

23   specific order in which would he do things, in point of

24   fact, those are the -- that is the sort of order he

25   would do things in, if he had time to do them in that

1   order. And due to the dynamics of the situation, these

2   things can take place in a variety of orders.

3   MR. BARRIE: A. Perhaps I should add as

4   well, I perhaps gave the impression that you would`do

5   them one, two, three, four, five. If you knew you were

6   in a certain situation, you might do half of all of

7   them immediately.

8   I gave a sequence which -- I was trying

9   to imply the kind of priorities we have. But there is

10   nothing to stop the operator doing a number of them

11   simultaneously, or a part of a number of them

12   simultaneously.

13   MR. SNELSON: A. And just to give you an

14   idea, I think he mentioned this, but public appeals

15   take some time to be effective. So if you expect to

16   have a problem say at 5:00 in the evening peak, you

17   would have to make a public appeal probably before noon

18   to be effective.

19   If you invited that time to be reckoning

20   on reducing the voltage at the time of peak, but if the

21   peak load doesn't actually materialize or some

22   additional generation becomes available, then you would

23   do the voltage -- the public appeal, but not the

24   voltage reduction. There are a variety of

25   circumstances and there are almost as many ways this

1   can happen as you can conceive of.

2   Q.   So in reality, we can be quite close

3   to the edge, as you were saying.

4   With respect to the F&D model.   What

5   threshold is used there?   Are we on the edge of the F&D

6   model, or is there a threshold built in?

7   A.   The F&D model--

8   Q.   Before--

9   A.   --assumes that rotating load cuts

10   will occur when there is insufficient capacity to meet

11   the load after having taken all those measures,

12   including allowing the reserve margin to go to zero.

13   So, there is a discrepancy here between

14   the F&D model and the operating practice of the order

15   of the 70 to 100 megawatts that Mr. Barrie has

16   described.

17

18

19

20

21

22

23

24

25   . . .

1   [12:50 p.m.] Q. Isn't it then fair to say that the

2   F&D model might underestimate the unsupplied energy

3   that will result from those rotating outages?

4   A. Yes. And I think it is fair to say

5   that if you would just mechanically carry this through

6   into an estimate of optimum reserve, it would show that

7   you would need of the order of 70 or 100 megawatts of

8   additional reserve, which is of the order of 1/2 a per

9   cent.

10   And I think there are many, many sources

11   in this calculation of uncertainties of the order of

12   1/2 a per cent or larger.

13   Q. You would take care of this through a

14   judgment factor, if you will, then?

15   A. It is part of our judgment, yes.

16   Q. Thank you.

17   Mr. Snelson, you were helping us out with

18   the outages and their threshold in the F&D model. What

19   about the thresholds for the appeals and the voltage

20   reductions in the F&D model?

21   A. I am not familiar with the current

22   order that they have in the model.

23   Q. Could you get that for us?

24   A. I believe we could get that.

25   MR. TABOREK: A. Yes.

1   Q.   Thank you.

2   I would like to turn briefly to page 30

3   of Exhibit 137, which is page 103 of Exhibit 87 and

4   continuing over to page 104 of Exhibit 87.

5   At the bottom of that page, there is a

6   heading, "Cutting Interruptible Loads." And here in

7   the last line, you express the concern that actually

8   interrupting them - that is the interruptible loads -

9   to this limit would cause many of them to shift to

10   being firm customers.

11   Has Hydro considered any modifications of

12   the interruptible load programs to improve the

13   long-term reliability and availability of their demand

14   impact.

15   MR. SNELSON: A.   Yes.

16   Q.   Can you expand upon that?

17   A.   Well, I think I did mention yesterday

18   or early this morning that the terms and conditions for

19   discount demand service were given in Interrogatory

20   2.6.32.

21   And what was previously called CIL, for

22   capacity interruptible load, is in the process of being

23   changed to a new category of load called "discount

24   demand service," which has the intention of achieving

25   the same objective. And the terms for the customer

1   have been made to be more favorable, to encourage them

2   to remain interruptible customers even during periods

3   of significant interruption.

4   There are two changes, primarily, that

5   have been made: One is that the number of hours that

6   they can be interrupted - their contractual limit on

7   the number of hours that they can be interrupted has

8   been reduced; and the other is that the form of

9   compensation they get for being interruptible customers

10   has been changed.

11   Previously, the way they were compensated

12   was by a discount on their demand part of their

13   electricity bill, and they received that discount month

14   in, month out, whether or not they were disconnected.

15   And during periods of good reliability, this was a real

16   bargain; you got a discount and you didn't get

17   disconnected.

18   With that set of conditions, then the

19   customers who have perhaps been accustomed to the

20   discount but not been disconnected, some of them got a

21   little upset when we started to have significant

22   disconnections, even though those disconnections were

23   within the contractual terms that they had agreed to.

24   And so, the discount is now given in two

25   ways: A smaller discount, I believe, on their demand

1   charge, plus they are given an amount for each

2   kilowatthour of demand that is interrupted, which is

3   given only at the time they are interrupted, and I

4   believe that amount is 10 cents a kilowatthour.

5   MR. TABOREK: A. Yes.

6   MR. SNELSON: A. So this substantial

7   amount is in excess of what they would pay for of the

8   rate for electricity. And this has two effects: One,

9   it encourages the customers to remain interruptible

10   during the times when they need to be interrupted when

11   we really need them.

12   And the second effect is that it actually

13   gives our operators some incentive to look for other

14   sources of electricity that will cost less than 10

15   cents a kilowatthour to avoid interrupting them.

16   I think a fuller discussion of discount

17   demand service would probably be better given by Panel

18   4; it is a demand management option.

19   Q. I just had two brief questions. You

20   were mentioning some of the terms that make the

21   contracts more favorable to the customer in the context

22   of DDS.

23   Have you looked at any terms, such as

24   specifying a minimum number of interruptions each year,

25   which would have the purpose say of screening out

1   participants who only want the discount but don't want

2   the inconvenience?

3   MR. TABOREK: A. You mean give it to

4   them whether it has to be done or not - they are going

5   to be interrupted regardless?

6   MR. BARRIE: A. It is not our policy,

7   no.

8   MR. TABOREK: A. Is that what you meant?

9   MR. SNELSON: A. I don't think that

10   would be very popular with the customers.

11   Q. So that hasn't been looked at all?

12   A. There were a variety of things that

13   we looked at when the terms were being revamped for

14   discount demand service. And as I say, I think Panel 4

15   is better qualified to discuss that. It is a demand

16   management option. It was dealt with by our Energy

17   Management Branch. But both operations and planning

18   were consulted in that process.

19   Q. Okay. What about tying the term of

20   the contract to the lead time of the gas turbine unit?

21   MR. BARRIE: A. That is done.

22   Q. That it is already done?

23   MR. SNELSON: A. We have insisted on

24   that from planning, that a customer who wishes to take

25   capacity interruptible load cannot divert to firm load

1   immediately. And I am not sure what is in the discount

2   demand service terms, but under the previous capacity

3   interruptible service, I believe that they had to give

4   out a two- or three-years' notice of their return to

5   firm load. And at the end of that period, they could

6   become firm load, but they were in a separate category.

7   They were still the first firm loads that

8   were interrupted for a remaining period to take it up

9   to five years. So essentially, they couldn't become

10   fully firm until five years. And that was intended to

11   make sure that we had the time, if necessary, to add

12   some form of generation or to contract for the purchase

13   or whatever, to respond to their need for firm power.

14   MR. BARRIE: A. Could I add, that is in

15   the demand discount service as well and it is still

16   five years.

17   Q. Yes. Thank you.

18   One more question before we leave this

19   section: Can the steam and electricity supplies to

20   heavy water plants be interrupted without curtailing

21   generation from the nuclear plants?

22   MR. TABOREK: A. Yes.

23   MR. BARRIE: A. It depends. (Laughter)

24   MR. SNELSON: A. I am not sure you are

25   getting questioned the right way around. (Laughter)

1   Q. Ms. Ryan? (Laughter)

2   MS. RYAN: A. Do you want four different

3   answers?

4   Q. Please go ahead.

5   MR. SNELSON: A. I think what you said

6   was, can the steam demand be curtailed without

7   interrupting electricity demand?

8   Q. No. My question was: Can the steam

9   and electricity supplies to your heavy water plants be

10   interrupted without curtailing generation from your

11   nuclear stations?

12   A. And I believe the answer is yes.

13   MR. BARRIE: A. Yes.

14   MR. SNELSON: A. We had --

15   MR. BARRIE: A. I will take back "It

16   depends." Yes.

17   Q. Okay. For how long?

18   MR. SNELSON: A. If you shut down heavy

19   water production, indefinitely.

20   MR. TABOREK: A. The heavy water plant

21   has an auxiliary fuel supply that can be used to

22   continue operations, albeit imperfectly. And in

23   practice, what happens with the heavy water plant is

24   that the steam is basically used to maintain the system

25   in a reasonable position for a comeback, such as to

1   prevent -- excuse me, the steam, the fuel, the

2   auxiliary fuel -- such as, for instance, to prevent

3   freezing if it were to happen in winter, for instance.

4   MR. SNELSON: A. We did point out in

5   Table 2 of page 11 in Exhibit 137 that the the letters

6   BHWP stand for Bruce Heavy Water Plant.

7   Q. Yes.

8   A. And that is the interruption of the

9   the electrical load. And that is considered to be an

10   interruptible load. It just happens to be an Ontario

11   Hydro-owned interruptible load.

12   MS. PATTERSON: So, for how long could

13   that be interrupted?

14   MR. TABOREK: As long as you were willing

15   to accept the interruption in the production of heavy

16   water.

17   MR. WATSON: Q. Well, how long is the

18   nuclear station willing to accept that?

19   MR. TABOREK: A. The nuclear station

20   will run independent. You could think of it as a

21   factory somewhere shutting down. And the nuclear

22   station will run happily whether that factory has its

23   power on or off.

24   Q. Doesn't the nuclear station need the

25   heavy water that is being produced?

1   A.   Oh, that is heavy water that was

2   produced in the years before the nuclear station came

3   into service.

4   So, for instance, now the heavy water

5   that is being made at Bruce is going to Darlington.

6   Now, there is some makeup that goes back to the other

7   stations, but there is an inventory. The heavy water

8   for the Bruce plant was typically made in the ten-year

9   period leading up to the opening of the Bruce plant.

10   Q.   Okay. You are making heavy water

11   today?

12   A.   Yes.

13   Q.   And --

14   A.   For Darlington and for loss makeup.

15   Q.   All right.

16   A.   What that means is it is for

17   Darlington, for all intents and purposes.

18   Q.   And you mentioned that one of the

19   things that would occur if you had lost the ability to

20   make heavy water would be that you would rely on your

21   inventory?

22   A.   Yes.

23   Q.   How long would your inventory last?

24   MR. SNELSON: A. For makeup?

25   Q.   Yes.

1   ⁓   A. Several years.

2   Q. Several years?

3   A. Yes.

4   MR. WATSON: Okay. Thank you. I am

5   about to turn to another area, Mr. Chairman.

6   THE CHAIRMAN: We will adjourn until

7   2:30.

8   THE REGISTRAR: This hearing will adjourn

9   until 2:30.

10   ---Luncheon recess at 1:04 p.m.

11

22

23

24   ...

25

1   ---On resuming at 2:37 p.m.

2   THE REGISTRAR: This hearing is now in

3   session. Please be seated.

4   THE CHAIRMAN: Once more this afternoon

5   we have to stop around 4:30.

6   MR. WATSON: Could I have one minute,

7   please?

8   MRS. FORMUSA: With Mr. Watson's

9   permission, I have here a number of interrogatory

10   undertakings that were given for Panel 1. I have the

11   eight copies for the panel, copies for all the parties

12   that participated in Panel 1 are placed in their

13   mailbox is or sent to them.

14   If I might, I can give them to Mr. Lucas

15   now and they will go into Exhibit 134. Each of them is

16   numbered pursuant to the undertaking that was given,

17   134.1. They are not all here. There are about ten of

18   them.

19   THE CHAIRMAN: How many more are to come,

20   do you know?

21   MRS. FORMUSA: No, I don't. But there

22   are about ten here. I will give them to Mr. Lucas.

23   THE CHAIRMAN: If they can be marked as

24   you have marked them.

25   Thank you, Mrs. Formusa.

1   Mr. Watson?

2   MR. WATSON: Q. Panel, if you could turn

3   to page 32 of Exhibit 137, dealing with customer

4   interruption cost. Page 32 and the following page,

5   32A, deal with these costs.

6   THE CHAIRMAN: And they come again from

7   Exhibit 87, do they?

8   MR. WATSON: They do, Mr. Chairman.

9   That's page 81 and 82 of Exhibit 87.

10   THE CHAIRMAN: Thank you.

11   MR. WATSON: Q. Those pages mention

12   customer surveys and those surveys were done to attempt

13   to determine the customer interruption cost.

14   Could you tell us the dates of those

15   surveys? It says between '76 and '79, is that the best

16   information?

17   MR. TABOREK: A. Well, there was a

18   series. The original Ontario Hydro series was done

19   over that time period. And further information is in

20   Exhibit 140, I believe, which will make it a little

21   more precise.

22   Then there is also a reference to surveys

23   done by the University of Saskatchewan and the Canadian

24   Electrical Association. Now it says in the '80s, well,

25   it was actually I believe '84/85, in that period, where

1   two of the areas in which Hydro had received some

2   questionable results; namely, farms and residences were

3   refined with University of Saskatchewan/CEA surveys.

4   Q.   Mr. Taborek, you mentioned that

5   University of Saskatchewan updated the surveys and you

6   also mentioned the Canadian Electric Association?

7   A.   Yes, they are the same survey but

8   they were done -- I think the CEA commissioned the

9   University of Saskatchewan to do the surveys.

10   Q.   They are the same survey, though?

11   A.   Yes, yes.

12   Q.   And only the residential and farm

13   sectors have been updated since 1984?

14   A.   Yes.   There is some preparatory work

15   now in place to do new surveys, again the University of

16   Saskatchewan with the support of electrical utilities.

17   Q.   Is that ongoing or is or that

18   something that will occur in the near future?

19   A.   It is starting and it will occur in

20   the near future.

21   Q.   And those surveys are the basis for

22   the information which is at a Table 4.8 on page 32A of

23   Exhibit 137; is that correct?

24   A.   Yes, and you will notice two

25   instances in which the University of Saskatchewan

1   information was substituted for Hydro's original

2   information.

3   Q. So, all of this information is from

4   '76 to '79, save for the University of Saskatchewan,

5   which is '84?

6   A. Let me just rephrase that. All of

7   the base information, and then there are two

8   adjustments made to bring it to the present day, one is

9   to escalate to allow for present day costs and the

10   other is to adjust for the present day mix of

11   electricity use by the different types of users.

12   Q. But that's based on the data set?

13   A. Based on the data set obtained

14   earlier, yes. I would mention, though, that in the

15   course of our review, we looked at information obtained

16   in our survey on other utilities, and that's reported

17   in Exhibit '87, and we felt that this remained

18   reasonable information to use.

19   Q. Why did you feel that?

20   A. Because, basically, it's an area - I

21   seem to be saying this a lot - where there is a good

22   deal of uncertainty in the information and the use of

23   the information, and that it is still reasonable.

24   Q. So, you feel it's reasonable. You

25   are conducting a survey in the near future to review

1   these numbers. Can you tell us when you think that

2   survey will be completed and when the new numbers will

3   be available. This year, for instance?

4   A. No, I can't, I'm sorry. I don't·

5   think it will be this year.

6   Q. Is this a one-, two-year project, or

7   could it be as long as three or four?

8   A. I'm sorry, I don't have that

9   information. I think you can see by that, I am not

10   waiting breathlessly to get it.

11   Q. Could you find out whether in fact

12   this is -- what sort of time frame we are looking at?

13   A. Yes, yes.

14   Q. When you conducted the original

15   surveys, what measures did you use to ensure the

16   reliability of the results?

17   MR. SNELSON: A. I doubt that Mr.

18   Taborek can recall because he was not involved in the

19   area at the time. I was involved in the area at the

20   time and my recollection is a little hazy.

21   The survey results are documented more

22   fully, as I said this morning, in the SEPRAS, that

23   system expansion program reassessments study reports,

24   and my memory was in fact correct. It is attached to

25   Interrogatory 2.7.80, and it is the fifth interim

1   report that includes the reliability studies at that

2   time.

3   The studies were carried out by a team

4   from what is now our energy management branch but it

5   would have been the forerunner organization of that

6   because it didn't exist at that time, and they were

7   generally recognized at the time as being the most

8   thorough studies of customer damage costs that have

9   been done in North America, and they were widely quoted

10   among other utilities.

11   So, as to the exact specific details of

12   how it was done, I don't think we can recall, but they

13   were considered to be the best available at the time.

14   Q. Is it fair to say that you are going

15   to attempt to do a similar high quality job this time?

16   A. I am not familiar with the details of

17   what is underway at the moment. I believe it's a

18   cooperative effort between several utilities, and

19   whether it will end up being a check on these results

20   or whether it will end up substituting for these

21   results I don't know.

22   MR. TABOREK: A. Mr. Watson, we did

23   express that we had some reservations about the numbers

24   we obtained, and indeed some of the numbers we have

25   obtained we have not used. And even when we did use

1 them in the 1981 report, Exhibit 140, the report

2 purposely pointed out that these numbers should be used

3 with care.

4   And so you are using words like "quality"

5 and it would be nice to attach that to your work.

6 Again, I would be careful with the numbers.

7   I think I said in my direct that many

8 utilities in North America will not or have not used

9 total customer cost because of concerns they have with

10 the use of this information. We think it's useful and

11 we use it. We recommend others use it because it adds

12 a measure of analysis to an area that would otherwise

13 be pure judgment and difficult to get a hold of. But

14 having said that, it's an area in which the the

15 analysis is in its early phases. Like, I think Hydro's

16 work was pioneering, wasn't it, this initial work?

17   MR. SNELSON: A. As I understand it, it

18 was one of the first such studies in North America.

19 There had been some similar work in Europe that

20 preceded it.

21   MR. TABOREK: A. And so this discipline,

22 if you will, is in its infancy.

23   Q. Mr. Snelson, you referred us to

24 Interrogatory 2.7.80, we will look at that, but will

25 that interrogatory help us with the number of customers

1   that were surveyed, the response rate, the number of

2   usable responses? For instance, a 90 or some other

3   percent confidence band, will it have that level of

4   detail?

5   MR. SNELSON: A. I am just scanning it

6   at the moment, and I doubt it would have that degree of

7   detail. I don't see it, on scanning the report.

8   Q. Could we get you to provide that

9   information if it is not too difficult to find?

10   MR. TABOREK: A. This again may be

11   difficult to find because it could well be buried in

12   archives.

13   Q. Your track record is quite good.

14   THE CHAIRMAN: When was this survey done?

15   MR. TABOREK: 1976 to 1979.

16   THE CHAIRMAN: And it was done outside

17   your organization, was it?

18   MR. SNELSON: It was run from within the

19   forerunner of our energy management branch. So, there

20   was a multi-branch task group doing the study.

21   The planning people, myself included, had

22   some input to the definitions of what was going to be

23   studied, and so on, and the interpretation of the

24   results, but the work was run from within, as I say,

25   the forerunner of our energy management branch. So, it

1   won't probably in our own files. It will be in other

2   branch's files if they are still accessible.

3   MR. WATSON: Q. Again, perhaps you could

4   let us know if you can find that information.

5   MR. SNELSON: A. Okay.

6   Q. What you might also do, if it is

7   readily available, is give us the terms of reference of

8   the new survey that you are proposing.

9   A. Yes.

10   MR. TABOREK: A. That is available.

11   Q. Thank you.

12   Mr. Taborek, I would like to explore, a

13   little bit, the statement that you made earlier about

14   the effect of higher or lower customer damage cost, and

15   that is at page 33 of Exhibit 137. That's page 96 of

16   Exhibit 87. And the sentence I am referring to is at

17   the very bottom of the page:

18   "Doubling the customer cost would

19   increase the optimum target reserve by

20   about one per cent. Halving the customer

21   damage costs would reduce the target

22   reserve by about two per cent."

23   Can you describe the process by which

24   this sensitivity analysis was conducted?

25   A. Yes. If you go back to Figure 5.1.

1   Q.   And if we could just take a minute.

2   That is on page 10 of Exhibit 137.

3   A.   The customer damage costs will shift

4   the slanting lines to the right if they are higher and

5   to the left if they are lower.

25   ...

1   [2:47 p.m.]   Q. Didn't you do any computer runs or

2   any sort of analysis to determine the figures that were

3   used in those quotes?

4   A. In those quotes? Sorry? What do you

5   mean?

6   Q. I quoted from page 96, and you are

7   talking about the interaction between doubling customer

8   damage costs, and the effect on the target reserve

9   margin. You come up with figures of one per cent if

10   you double the cost, and two per cent if you halve it.

11   I mean, where do those figures come from?

12   A. The one and the two per cent, or the

13   doubling and the halving?

14   A. All of them.

15   Q. Well, the doubling and the halving is

16   a traditional technique you use when you wish to study

17   the sensitivity of a parameter in which there is some

18   uncertainty you'd like to get ahold of. It happens

19   that the doubling approximately takes you to the cost

20   for a 15 minute rotating load cut, so it had some

21   relevance there. So those are the reasons for doubling

22   and halving.

23   Q. And you mentioned a sensitivity.

24   That is what I'm trying to explore.

25   A. Because we wanted to know the

1   sensitivity of the reserve margin to changes in that

2   input number, roughly $6 a kilowatthour. So, having

3   established what the range of inputs would be, it is

4   merely multiplying by those different dollar numbers to

5   get the shift in the curve.

6   Q. To get the either one per cent or two

7   per cent?

8   A. And the curves will shift to the

9   right for the higher, and they will shift to the right

10   about one per cent, and they will shift to the left

11   about two per cent.

12   Q. So you didn't have to do any

13   additional F&D model runs to deal with this?

14   A. No, because the unsupplied energy is

15   the same in these runs. It is the cost to the customer

16   of that given unsupplied energy. So, it is a very

17   quick and easy thing to do.

18   Q. So, in effect, what we are saying

19   here is that the target reserve margin is just not very

20   sensitive to outage cost assumptions?

21   A. That is correct. If, and the big

22   "if" is if you are working with a reserve margin that

23   takes you near minimum total customer cost, because as

24   we have said a number of times, and you have seen in

25   various figures, that at the minimum total customer

1   cost, there is very little rotating load cuts. And

2   since there is very little, you can multiply it by what

3   you will, and you are not going to change things very

4   much.

5   And that is also one of the reasons why,

6   while we feel that there is a great deal of uncertainty

7   in these numbers, when they are being used in this

8   fashion, you can still tolerate that uncertainty and

9   come to a reasonable conclusion, because of the nature

10   of the relative size of the numbers. And that was why,

11   I said - perhaps, too flippantly - that while we were

12   looking forward to getting the information from the new

13   survey, it wasn't a critical thing to us to get it,

14   because of just this underlying fact.

15   Q. In effect, the insensitivity, to put

16   it in terms of figure 5.1, occurs because the slope of

17   the curves is very steep at the cross-over point, isn't

18   that correct?

19   A. Yes. And it steepens -- well, no, I

20   think maybe that was too quick an answer. It is

21   because the amount of unsupplied energy in rotating

22   load cuts at minimum total customer cost is quite

23   small. If you recall, when we were looking at Table 2,

24   we didn't put a number on it, we put a star and said it

25   is near zero and that our target of system minutes, 10

1   or 25 or whatever, is mostly uncosted assumptions about

2   emergency measures.

3   So, it is the fact that your optimum

4   comes about with little in the way of load cuts, or the

5   customer's value load cuts to the point where you don't

6   have to go very far to make it worthwhile to protect

7   them from it, that means it is not significant or it is

8   not sensitive.

9   Now then, if you were to cut the reserve

10   margin to where you were giving customers a substantial

11   number of load cuts, then you would find that your

12   assumptions about the value customer's place on load

13   cuts would be very critical in determining what your

14   margins are, your optimal positions.

15   And the other thing I would suggest also,

16   that if you do a survey of customers after a period in

17   which they have had no load cuts, and then you do a

18   survey of customers after a period in which they have

19   had a lot of load cuts, you might get some surprises,

20   too.

21   Q. So are you saying the slope of the

22   curve is not one of the reasons for the insensitivity?

23   A. I think that is correct. It is not,

24   the slope, but the small amount of system minutes that

25   result in the near optimum position, as I understand

1   it.

2   Ken, would you...

3   MR. SNELSON: A. I think the shape of

4   the curve has something to do with it. But, is as true

5   with a lot of these reliability calculations that

6   things change quite rapidly. If you have a system 25

7   per cent reserve, and you reduce the reserve level 20

8   per cent, then a lot of measures, such as unsupplied

9   energy, might go up by a factor of 10 per cent. You

10   reduce it by another five per cent, and it is now up by

11   another factor of ten, say, a hundred; it is a kind of

12   an exponential type of relationship to a lot of these

13   parameters. It tends to mean quite wide variations and

14   some of the parameters tend not to shift the reserve

15   from our margin that is optimal a very long way.

16   Q. Perhaps how we could deal with this,

17   sir, there appears to be a little bit of disagreement

18   here.

19   MR. TABOREK: A. I don't think there is

20   a disagreement. I think we are saying the same thing

21   from slightly different directions, that is all. We

22   are describing the elephant from the front and the

23   back. We are still describing the elephant.

24   Q. Okay, I just wanted to make sure I

25   was looking at the same elephant.

1   A.   There is actually an illustration in

2   figure -- in Exhibit 140, where the effect of customer

3   damage costs of two different levels are shown, and...

4   Q.   Where is that again, Mr. Taborek?

5   A.   Okay, it is Exhibit 140, and figure

6   2.6. I suspect it will also appear in other figures,

7   but that is a convenient one.

8   If I remember the chronology here, it

9   shows a SEPRA estimate, and it shows a 1980 estimate.

10   The SEPRA estimate was for only some of the categories,

11   and it did not have in it the large farms, office

12   buildings, retail, government agencies. What it had in

13   it was residential, small industrial and large users.

14   So, they came out in batches.

15   And the upshot of that is the SEPRA

16   estimate was low, and then the next batch of estimates

17   came in, and this included some of the very high ones,

18   like the large farms. So, they boosted the numbers.

19   When you look at this curve, in the way

20   we have been discussing, one of the things you are

21   interested in doing is looking at the minimum for the

22   minimum total customer cost. And what you see is that

23   in the region of low reserve margins, in which you have

24   high unsupplied energies, then the magnitude of the

25   customer damage cost has a big effect. But as you move

1   to higher levels of reliability, and the amount of

2   unsupplied energy that you are costing drops, the

3   difference between the costs, the higher and the lower

4   estimates, rapidly disappears, until in this case, at

5   about the 26 per cent level, it disappears totally.

6   Ken was, I guess, discussing the slopes

7   to the left, and the rapidity with which the customer

8   damage costs rise and the unsupplied energy rises, as

9   you get into trouble, this cliff that we had mentioned,

10   and I was discussing the other end of this elephant, in

11   the region of the optimum, in which there is very

12   little costed unsupplied energy, and hence the unit

13   costs are not significant.

14   Q.   Thank you.

15   A.   Not "significant"; it is -- the word

16   sensitive.

17   Q.   Sorry?

18   A.   Sensitive is a better word than

19   significant.

20   Q.   Has Hydro valuated the sensitivity of

21   the target reserve margin to the CTU cost?

22   A.   Well, you can do it by eye on figure

23   5.1, in essence, by applying factors above and below.

24   You can just scale it off just by eye. If you drop it

25   ten per cent, raise it ten per cent, you can just scale

1   it off the figure. And if you want to try...

2   Q. Thank you. Does Hydro use customer

3   interruption cost data for other purposes such as rate

4   design?

5   MR. SNELSON: A. Other purposes, yes. I

6   don't believe so for rate design. There is nobody on

7   this panel who is expert in rate design.

8   Q. Can you tell us what those other

9   purposes are?

10   A. I believe they are used in certain

11   aspects of the design of the regional supply system and

12   in some specialized cases. They may also be used as an

13   operating aspect, but Mr. Barrie would be more expert

14   on that than I.

15   MR. BARRIE: A. I'm not aware of them

16   specifically being used. Maybe in the regional supply,

17   by regional supply, we mean not the integrated system

18   that I have been referring to.

19   Q. Thank you. I'd like to turn now to

20   load forecast uncertainty. Panel, could you turn to

21   page 34 of Exhibit 137? That is page 70 of Exhibit 87.

22   You will see that page 70, we have Table

23   4.4, which is standard deviation of historical errors,

24   per cent of actual peak load. There is a series of

25   lead time years from one to eight, and then two columns

1   of standard deviation data.

2   Does the standard deviation of load

3   forecast uncertainty, which is used as an input for the

4   F&D model, come from this table, Table 4.4?

5   MR. TABOREK: A.   Yes.   It is the No.

6   8.8, which occurs in the column "Standard Deviation

7   About Sample Average," and at the row for four years.

8   Q.   Mr. Taborek, you have referred us to

9   the row that is at four years lead time, and the figure

10   8.8 is under "Standard Deviation About Sample Average."

11   Continuing along that row, there is a figure of 9.1

12   under standard deviation of zero.   Why is there a

13   difference between those two values?

14   A.   Because the mean of the sample is not

15   at zero, or you can -- in Exhibit 87, figure 4.1...

16   Q.   That is just after page 92?

17

18

19

20

21

22

23

24   ...

25

1   [3:03 p.m.]   A.   Yes.   It shows the actual

2   distribution of errors and the difference between the

3   mean of the sample and having the standard deviation

4   taken about the zero point.

5   Q.   Do the differences between those two

6   columns of figures imply a systematic bias in

7   forecasting errors, either underforecasting or

8   overforecast?

9   A.   In this time period, yes.

10   MR. SNELSON: A.   I think one would have

11   to do a statistical test to see whether that showed a

12   statistical bias.

13   The fact that you have taken a random

14   sample from a group of data which has no bias and that

15   the sample has a mean other than zero doesn't

16   necessarily mean that the population it is taken from

17   has bias.

18   MR. TABOREK: A.   I defer to Mr.

19   Snelson's answer.

20   Q.   Have you done that analysis, Mr.

21   Snelson?

22   MR. SNELSON: A.   This is the sort of

23   question that was looked at by Mr. Burke in his

24   assessment of ranges above forecast.

25   In this particular case, the deviations

1   between the distributions and the difference between

2   the 8.8 and the 9.1 is really quite small.

3   Q.   It isn't in year eight, though?

4   A.   That's correct.

5   MR. TABOREK: A.   That is one of the

6   reasons that it is a very good idea to have short lead

7   times for your reliability planning, to have your

8   approvals in hand so that you can build quickly because

9   otherwise, you have to plan for very long lead times

10   and higher and more uncertain errors.

11   MR. SNELSON: A.   Well, I think Mr.

12   Burke's evidence has been that there was a major

13   deviation in the 1970s and that he has done analysis on

14   load forecast errors.

15   And his analysis on load forecast errors

16   and prediction of load forecast errors is more detailed

17   and superior to a simplistic analysis that might come

18   from just a straight plotting of historical errors.

19   Q.   Okay. Mr. Taborek, you had referred

20   us to Table 4.1, the very next page -- sorry, Figure

21   4.1.

22   The very next page is Figure 4.2 and that

23   is at page 35 of Exhibit 137. That is a graph titled,

24   "Comparison of Models, standard error with history."

25   What is the model that is referred to

1   there?

2   MR. TABOREK: A. The model that is

3   referred to is the F&D model and it is the information

4   that had previously been in the F&D model.

5   And the source of that information is

6   earlier techniques that the load forecast department

7   had used to describe load forecast uncertainty.

8   And I might just make a point: You have

9   noted that there are wide differences in the long-term.

10   And in the point of our review, we noticed that in the

11   four-year period in which we were forecasting with CTUs

12   as peaking units, there was very little difference in

13   those two approaches.

14   So we were pleased that we achieved that

15   kind of a convergence in the lead times in which we

16   were interested.

17   And we were also very pleased that we

18   would not have to deal with longer lead times. It

19   presented much more of a challenge.

20   Q. Panel, if you could turn to page 36

21   of Exhibit 137. That is page 73 of Exhibit 87. There

22   we have Table 4.6.

23   And just underneath that, there is a

24   sentence that says:

25   "At the four-year lead time, of

1   interest in this analysis, the results of

2   the historical analysis and that of Monte

3   Carlo analysis are almost identical."

4   Now, is the Monte Carlo analysis that is

5   described there the same as that which is used in

6   creating the load forecast bandwidth as described in

7   the D/SP?

8   A.   Not quite, but it is related to it.

9   We mentioned two particular approaches and we are

10   aware, of course, that Mr. Burke was working on a new

11   approach for describing the bandwidth.

12   Now, the approach that he is dealing with

13   is primarily dealing with the long-term --

14   Q.   Excuse me, Mr. Taborek, when you said

15   "the approach he is dealing with," is that the one that

16   is referred to in --

17   A.   That is he is developing and which is

18   used in the D/SP.

19   Q.   Thank you.

20   A.   It deals primarily with the

21   long-term.

22   And what we are looking for - and I think

23   Mr. Burke will have told you that and I will just give

24   you a bit of this because I am not an expert.

25   Mr. Burke is the best source - that when

1   he does his long-term forecasting, short-term

2   variations or cycles tend to be damped out. And his

3   route forecast is for an energy analysis, not a

4   capacity analysis, and it is a long-term steady state

5   trend mostly linked to population, if I may crudely

6   simplify his approach.

7   In the short term of four years, it is

8   important for us to take account of the these cycles,

9   so we gave the results that we had from the previous

10   page to Mr. Burke and asked him to test it against his

11   new approach.

12   And he did and he developed this Monte

13   Carlo analysis where he introduced short-term

14   uncertainties and he advised us that at the four-year

15   lead time, he had a number like 8.6 where we had a

16   number like 8.8. And so, we were again pleased to see

17   that the numbers on load forecast uncertainty were

18   coming into the same region.

19   Q. If we look at Table 4.6 on the same

20   page, we can do some quick analysis. If we look at the

21   eight-year lead time, we can see that the Monte Carlo

22   analysis gives us a standard deviation of 13.7 per cent

23   of the peak.

24   And to get an 80 per cent confidence

25   band, as I understand it, you take a figure of

1   approximately 1.4 and multiply that by your standard

2   error; is that correct?

3   A.   Well, I think you are taking me into

4   an area which is Mr. Burke's specialty, and this model

5   analysis is his, and I wouldn't really care to address

6   it.   I am not competent to address his area.

7   Q.   Mr. Snelson, are you comfortable with

8   dealing with confidence bands?   For instance, would you

9   be aware of the fact that to get a 95 per cent

10   confidence band, you multiply by roughly 1.96?   To get

11   an 80 per cent confidence band, you multiply by roughly

12   1.4?   Are you familiar with that?

13   MR. SNELSON: A.   These are confidence

14   limits under normal distribution, I presume.

15   Q.   Yes.

16   A.   And I would presume you have done

17   your arithmetic correctly.   I don't remember the points

18   on the normal distribution.

19   Q.   Well --

20   A.   But they seem to be of the right

21   order of magnitude.

22   Q.   Okay.   Perhaps we could just proceed,

23   subject to you checking those figures.

24   My understanding is that those figures

25   are the appropriate figures.

1   A.   I think the point here is that the

2   only numbers in that table that have been used in the

3   analysis are the four-year lead time numbers.

4   Q.   Okay.

5   MR. TABOREK: A.   We are, in effect,

6   pointing out that there is some uncertainty in the

7   longer-term numbers, but we just note it.

8   Q.   Well, I would like to proceed with

9   both the eight-year and the four-year, if you don't

10   mind, and if we get beyond your level of understanding,

11   please let me know.

12   MR. SNELSON: A.   Well, we can deal with

13   it from a theoretical point of view as regards to the

14   relationship to the load forecast bandwidth, then I

15   don't think either Mr. Taborek or myself can usefully

16   comment on that.

17   Q.   Well, let's see how far we get.

18   If, in fact, we are talking about the

19   eight-year lead time, an 80 per cent confidence band

20   would be 1.4 times 13.7 per cent, which would give us

21   roughly plus or minus 19 per cent.

22   And if the historical values were used,

23   it would be 1.4 times 18.2 per cent, which would give

24   us approximately plus or minus 26 per cent of the peak.

25   In other words, using those figures, an

1   80 per cent bandwidth would produce a median, plus or

2   minus the 26 per cent for each limit. And again, I

3   would very much welcome you checking those figures.

4   If you could turn to the next page of

5   Exhibit 137, and that is page 37, you will see figure

6   3-12, which is the '88 basic load forecast bandwidth.

7   And if, in fact, we go through the same

8   analysis, eight years out would be for 1996. And you

9   can see the figures in the bandwidth are 24.2 for the

10   low, 28.1 for the median, and 31.6 for the upper.

11   Taking those figures, I get a median and

12   bandwidth of 28.1, plus or minus approximately 13 per

13   cent.

14   Just doing that quick arithmetic --

15   THE CHAIRMAN: The formula that you have

16   come up with, I don't recall that in Mr. Burke's

17   evidence.

18   Is that where you derive that formula

19   from that you just mentioned? What is your source of

20   that formula?

21   MR. WATSON: Are you talking about--

22   THE CHAIRMAN: The 1.4.

23   MR. WATSON: --the 1.4? I believe that

24   is reasonably standard statistical theory.

25   THE CHAIRMAN: Well, I don't recall it.

1   Mr. Burke spent a great deal of time describing how

2   they created the bandwidth. And I may have overlooked

3   it, but I just don't remember it being reduced to those

4   simple terms.

5   MR. WATSON: Well, perhaps we could leave

6   it with the witnesses.

7   If, in fact, that interpretation that I

8   have put forward or that mathematics that I have put

9   forward is incorrect, they could let us know.

10   THE CHAIRMAN: All right.

11   MR. WATSON: It is my understanding that

12   that is --

13   MR. SNELSON: This, I think, is a Panel 1

14   issue.

15   MR. TABOREK: Yes. I would rather not

16   discuss it at the eight years, but the four years, we

17   will...

18   MR. WATSON: Well, we can do the same

19   analysis with the four years and I was going to do that

20   as well.

21   Q. And as you suggest, Mr. Taborek, if

22   you are more comfortable with the four years, I can go

23   through exactly the same numbers with the four years.

24   And doing exactly the same thing, you

25   take the numbers for the four-year lead time in Table

1   4.6, and instead of the 13.7 number, you would use 8.6.

2   For the Monte Carlo, instead of 18.2, you

3   would use 8.8 for the historical.

4   And then on Figure 3.12, going out four

5   years, you would be into the 1992 figures.

6

7

8

16

17

18

19

20

21

22

23

24   ...

25

1   [3:15 p.m.]   MR. TABOREK: A.   I think I have said

2   that the technique Mr. Burke uses in developing the

3   bandwidths are long-term, and they tend to damp out

4   short-term perturbations. And he, in effect, developed

5   a special approach suitable for the short term of this

6   general technique, to use in comparing with the various

7   estimates we had. And that the technique he developed,

8   which is called Monte Carlo, in the four-year lead

9   time, fit reasonably with the two other sources we had

10   for an estimate of this number.

11   So, it is not appropriate to take Figure

12   3.12 and apply it against, though, because it was

13   developed for different purposes. It was developed for

14   long-term forecasting.

15   Q.   It may have been developed for

16   long-term forecasts. It does give values from 1989 on.

17   And certainly, in going through the values, as I did in

18   some detail, for the eight-year lead time, you see a

19   significant difference between the results--

20   A.   Yes.

21   Q.   --between the two results of the

22   Monte Carlo analyses.

23   A.   Which in my understanding in

24   discussing it was due to the fact that the short-term

25   variations have not been included in 3.12 and hence

1   there is less variation, in that the short-term

2   variations are included in Table 4.6, and that that's

3   what accounts for that difference.

4   Q. Is your answer the same for the

5   four-year lead time?

6   A. It's only with respect to the

7   four-year lead time. That's the only time I am

8   answering with respect to.

9   Q. Okay. And can you help us all as to

10   why the difference would be so large or even larger in

11   the eight-year time frame?

12   A. No.

13   Q. Mr. Snelson, can you...

14   MR. SNELSON: A. I can't help you.

15   Q. How is load forecast uncertainty

16   represented in the F&D model? Is a discrete

17   approximation used?

18   MR. TABOREK: A. No. Our most recent

19   developments have been to, in effect, utilize various

20   levels of load forecast uncertainty and to run the F&D

21   model, I think it is, approximately 21 times at 21

22   different levels of load forecast uncertainty, and to

23   take the results from this multiple running.

24   This was an essential part of being able

25   to determine, in our way of thinking, the energy limits

1   on the hydraulic, it was an essential lead to that.

2   Q.   Are all 21 of these weighted equally?

3   A.   They are weighted according to the

4   probability of their occurrence.

5   Q.   A simple weighting technique, as we

6   saw earlier?

7   A.   Yes. It's, in effect, an expected

8   technique in decomposing it into its components.

9   Q.   Would you refer to page 38 of Exhibit

10   137, please? That's figure 15-45 from the D/SP. This

11   curve shows the 24 per cent target reserve margin being

12   met for all three scenarios after a transient period.

13   Now, as I understand it, the target

14   reserve margin of 24 per cent assumes a certain load

15   forecast uncertainty; is that correct?

16   A.   Yes.

17   Q.   I guess the difficulty I am having is

18   that if you apply a 24 per cent target reserve margin,

19   with its assumption of load forecast uncertainty, and

20   apply that to, for instance, the high demand scenario,

21   the upper band, if you will, which is at the upper end

22   of the 80 per cent uncertainty band -- in effect,

23   aren't you double-counting the load forecast

24   uncertainty?

25   A.   Well, not if you are on the high

1   scenario.

2   Q.   What if you are not?

3   A.   Then you would be applying it to the

4   scenario in which you are on. You would adjust -- I

5   might mention, incidentally, that for much of -- I'm

6   sorry, I will stop there.

7   Q. Sorry?

8   A.   I was going to say something that

9   wasn't really relevant.

10   Q.   I am not sure I understand. I was

11   concerned about whether there was some double-counting

12   there.

13   MR. SNELSON: A.   I don't believe there

14   is. The upper load growth scenario is based on the

15   assumption that the load follows the upper bandwidth of

16   the load forecast bandwidth. And in deciding on how we

17   would react to that, we did not assume that we would

18   know immediately that we were on an upper load growth

19   scenario and thereby plan accordingly. We assume some

20   sort of delay, and that delay was of the order of a few

21   years. And during that period, you would suffer the

22   uncertainty that is modelled in the F&D program.

23   In fact, you would probably continue to

24   suffer that, because, even though you are on a high

25   load growth scenario, you probably wouldn't suddenly,

1   in a flash of inspiration, realize that your load

2   growth is now four per cent instead of two per cent.

3   You are going to successively, over a period of years,

4   gradually increase your load forecast as you build in

5   your evolving knowledge about the new trend.

6   And we allowed the reserve level to slip

7   in the upper load growth scenarios to about 20 per

8   cent, on the assumption that either we couldn't build

9   plant fast enough, or we wouldn't realize that we

10   needed to build plant fast enough, and we didn't really

11   have to decide which of those circumstances was driving

12   it.

13   But we did model in that circumstance for

14   most of the period about a 20 per cent reserve. And

15   you will notice on that figure that, in the period

16   before we can respond, the reserve drops below 20 per

17   cent.

18   Q. You are referring to the 20 per cent

19   figure. How did you decide on 20 per cent?

20   A. It was a judgment based on the

21   overall judgment that reserve levels should be in the

22   20 to 24 per cent range. In the median load forecast,

23   if things are developing as you expect, then we have a

24   preference for leaning towards the upper end of that in

25   terms of reserve margin, and that's in the median

1   forecast was prepared on 24 percentage. I think we

2   have given a number of reasons why we prefer to be

3   towards the upper end.

4   In the situation of high load growth, we

5   would be scrambling and we would be struggling to

6   maintain even an adequate reserve margin of 20 per

7   cent. So, it was a judgment.

8   Q. So, you are saying you would be

9   struggling, so you determined that would be your

10   absolute minimum and you just couldn't go below that?

11   A. We would struggle much harder to keep

12   the reserve above 20 per cent than we would to increase

13   the reserve from 20 to 24.

14   MR. TABOREK: A. And you use the term

15   "absolute minimum." It is more that you are getting

16   into a region in which the risk of customer damage

17   costs rising sharply are beginning to hit you

18   -(coughing)- beginning to rise sharply.

19   Q. And that's what we were referring to

20   the other day, Mr. Taborek, when you were talking about

21   the slope, over on the far left-hand side of the curve

22   the slope is a lot higher--

23   A. Yes.

24   Q. --and you are concerned about moving,

25   a small change there will cause a large change.

1   A.   But nevertheless, in the region of

2   the minimum, you could make small adjustments away from

3   the minimum and still be on a relatively shallow part

4   of that curve. And it is only when you got off it some

5   way that you began to rise sharply. And our judgment

6   was that 20 per cent was a reasonable distance to the

7   left of the curve for a brief period of time, well,

8   brief in planning terms.

9   Q.   Throughout most of the upper growth

10 scenario, certainly from '94 to, say, 2004 --

11   A.   Brief in planning terms. (Laughter)

12   Q.   Through that brief period, you're

13 right at the 20 per cent reserve margin?

14   A.   Yes.

15   Q.   You then indicate that you would go

16 up to 24 percentage, continue along at that level

17 throughout the balance of the planning period.

18   A.   Yes. Although -- I'm sorry, I am

19 prejudging your question.

20   Q.   Please go ahead.

21   A.   In the early part of this time

22 period, we do not have an option to build new

23 generation to restore the reserve margin because there

24 is time for approvals, et cetera. And the first that

25 the new generation could appear is -- I forget the

1   first dates in the upper, but they are in Plan 15, and

2   so it's not the full 15 years in which we consciously

3   make that decision. The period up until then, we are

4   scrambling to put everything we have onto the system to

5   maintain 20, but we can't use new generation to do it.

6   Q. Are we close to the cliff again?

7   A. Twenty is getting close to the cliff.

8   Q. Is it possible that we could go below

9   20?

10   MR. SNELSON: A. Yes.

11   MR. TABOREK: A. Yes. It's this point I

12   mentioned a little earlier, the possibility you could

13   do very clever things with reliability and hit bad

14   luck, and you can do very foolish things with

15   reliability and have good luck. But your chances are

16   you will have bad luck.

17   Q. What you are saying in the upper

18   scenario is that in 2005, new supplies coming on line

19   and that brings you back up to 24 per cent?

20   A. Yes.

21   Q. So, if that new supply is delayed or

22   does not occur, you are at 20 per cent.

23   A. And it will be riskier.

24   MR. SNELSON: A. You have options to go

25   beyond the 20 per cent. The increase that is shown

1   here is the addition of base load generation resources

2   to raise the generation. There are various gas-fired

3   or oil-fired peaking options that can be obtained

4   faster than that. So those are still options.

5   Q.   The next page, page 39 of Exhibit

6   137, is the first page of Exhibit 87. We can see in

7   the last paragraph, in effect, you are saying that the

8   reserve margin varies from 22 per cent to 24 per cent

9   in the medium scenario. Does this mean that 24 per

10   cent is not your minimum reserve margin?

11   MR. TABOREK: A.   That's correct. It was

12   described as a target, and you cannot maintain it very

13   closely. So, when it fell below 24 per cent, we would

14   then add units, and that tended to take you in the 22

15   per cent range. And so it wasn't an absolute minimum.

16   Q.   What is a minimum acceptable reserve

17   margin? Is it 20 per cent?

18   A.   For what purpose? I think I need a

19   little bit of clarification about what you mean it for.

20   Q.   For the plan being put forward, case

21   No. 15 in the D/SP?

22   A.   20 to 24 per cent range.

23   Q.   So 20?

24   A.   Twenty is the minimum temporarily, 24

25   is the target, and to be in that range.

1   Q. If I could ask you to turn to page 40

2   of Exhibit 137. That's page 19 of the 1981 reliability

3   criteria.

4   THE CHAIRMAN: Which is Exhibit... ?

5   MR. WATSON: Which is Exhibit 140.

6   THE CHAIRMAN: Thank you.

7   MR. WATSON: Q. You can see under the

8   heading "Load Forecast Uncertainty," the last sentence

9   in the first paragraph:

10   "A change in the load forecast

11   uncertainty of 1 per cent point changes

12   the required reserve in the system by

13   approximately 2 percentage points."

14   Could you explain that for us, please?

15   MR. TABOREK: A. The load forecast

16   uncertainty is measuring for you how wrong you can be,

17   how much error you can make in your load forecast.

18

19

20

21

22

23

24   ...

25

1   [3:33 p.m.]   And the more error, the more uncertainty

2   that you have in your load forecast, the more reserve

3   margin you need to keep you in a region of acceptable

4   unsupplied energy or customer damage costs.

5   MR. SNELSON: A.   The one per cent change

6   in load forecast uncertainty that is referred to is a

7   one per cent change in the standard deviation due to

8   load forecast uncertainty.   And by the sort of

9   phenomena that you were describing to us a short while

10   ago, if you are talking about things that have a one in

11   ten chance or so of occurring, that is more than one

12   standard deviation away from the median.

13   The result of applying it to our model at

14   that time, and I don't expect the result to be very

15   much different today, that the result was that a one

16   percentage point change in the standard deviation of

17   load forecast uncertainty, a one per cent increase

18   resulted in about two per cent increase in optimum

19   reserve.

20   Q.   Just so I understand, when you say

21   two per cent, is that two per cent of the 24, or is

22   that an increase of two per cent on top of the 24?   In

23   other words, from 24 to 26?

24   A.   Twenty-four to twenty-six.

25   Q.   When the load forecast uncertainty

1   increases one percentage point, does that mean that-the

2   standard deviation increases from, say, 8.8 per cent to

3   9.8 per cent?

4   A. That is correct.

5   MR. WATSON: One final question before

6   the break, Mr. Chairman.

7   Q. Why isn't an increase in load

8   uncertainty matched one for one by an increase in

9   reserve margin?

10   MR. SNELSON: A. Because the reliability

11 of the system is driven by things that are further than

12 one standard deviation away from the median.

13   Q. Such as?

14   A. Well, we showed that in the '81

15 report that most of the problems that contributed to

16 the average unsupplied energy were in a bad year that

17 was a once-in-ten-year case, or something similar. It

18 is a few events that are relatively improbable that

19 drive the average. And these events tend to be

20 associated with load forecast errors of more than one

21 standard deviation.

22   MR. WATSON: Okay, I'm finished with that

23 area, Mr. Chairman.

24   THE CHAIRMAN: Take a 15-minute break.

25   THE REGISTRAR: The hearing will recess

1   15 minutes.

2   ---Recess at 3:36 p.m.

3   ---On resuming at 3:56 p.m.

4   THE REGISTRAR: Please come to order.

5   This hearing is again in session. Please be seated.

6   THE CHAIRMAN: Mr. Watson?

7   MR. WATSON: Q. Panel, earlier you were

8   referring to interconnection assistance. I'd like to

9   turn to that area now, please. I understand that

10   currently...

11   Panel, I'd like to turn to

12   interconnection assistance right now. I understand

13   that, currently, the reserve requirement on the system

14   is reduced by about 700 megawatts to allow for

15   emergency assistance from neighboring utilities.

16   MR. TABOREK: A. Yes.

17   Q. That is an approximation, as I

18   understand. Is there an exact number to go along with

19   that?

20   A. It is not an approximation. It is

21   the number that we use.

22   Q. So that is the number you use.

23   A. In the peak periods.

24   Q. Okay. So there is no more available,

25   or that is the maximum that is available?

1   A.   Well, we had mentioned that something

2   like 2,000 megawatts would be available off-peak, and

3   perhaps even more than that, if you were not

4   experiencing a load forecast correlated type of

5   problem, and it was perhaps a generation type of

6   problem.   And in that case, more might be available.

7   Q.   So when you referred, in the

8   reliability review of '91, when you say about 700

9   megawatts, the word "about" shouldn't be there.   It is

10   700 megawatts.

11   A.   Yes, and the word "about" is meant to

12   imply the degree of precision we would associate with

13   that number.   It is an estimate, but it is the

14   estimate.

15   Q.   How do you represent that in the F&D

16   model?

17   A.   There is a provision for purchases in

18   the model.

19   Q.   Is it a firm resource with perfect

20   availability?

21   A.   Yes.

22   Q.   Does that number change from year to

23   year?

24   A.   If you wish it to.   There is a

25   provision for it to change, but we did not change it.

1   We used 700 in the peaks.

2   Q. I notice in the '81 review you use

3   700 as well.

4   A. That is correct.

5   Q. Has that 700 figure been constant

6   throughout?

7   A. Yes.

8   Q. Well, does it necessarily follow that

9   nothing has changed in that period that would allow you

10   to change that number, or have you just not examined

11   that?

12   A. No, things have clearly changed. I

13   mentioned all kinds of things are changing all the

14   time. The changes, however, are not significant enough

15   for the degree of precision you can achieve. Precision

16   and degree of accuracy you can get with these estimates

17   are such that it is not -- we didn't feel it worthwhile

18   to attempt to refine that number.

19   Q. So, the changes weren't significant

20   then?

21   A. That is correct. The underlying

22   factors are still there, namely that our load forecast

23   errors are correlated with the load forecast errors of

24   neighboring utilities, and that that would tend to

25   limit the amounts that would be available to us in

1   those kinds of contingencies.

2   Q. I believe in reading somewhere, I

3   know that there was supposed to be a review of the 700

4   figure conducted in 1982. Do you know if that review

5   occurred?

6   A. No, I don't. I'm not aware of

7   anything since this time.

8   MR. SNELSON: A. I don't know where your

9   reference is taken from, and I'm not aware of the

10   review being done.

11   Q. Yes, if you look at Exhibit 140, page

12   10.

13   MR. TABOREK: A. Oh, it said, "It is

14   intended to."

15   Q. Yes.

16   A. I'm not aware that this was done.

17   Q. Sorry, that was the thrust of my

18   question. I understood there was to be a review in

19   1982, and I was curious as to whether that review had

20   occurred, and what the results would have been.

21   A. I'm not aware of it.

22   Q. Could you attempt to find out whether

23   the review did occur, and if so --

24   MR. SNELSON: A. I think you can take it

25   that a review did not occur, and we will get back to

1   you if that is not the case. But I'm pretty sure that

2   one or the other of us would be aware of it if it had

3   taken place.

4   Q. Panel, if you could turn to page 42

5   of Exhibit 137. That is figure 3.2 from the 1981

6   reliability review, Exhibit 140. Can you tell us how

7   that figure was constructed and whether a model was

8   used?

9   MR. TABOREK: A. I cannot.

10   MR. SNELSON: A. I have some

11   recollection of how it was constructed, yes, but not

12   the full details.

13   Q. Okay.

14   A. I believe there was a model.

15   Q. Perhaps you could get back to us on

16   that.

17   A. I believe it was a two-area loss of

18   load probability model.

19   THE CHAIRMAN: I'm having a little

20   trouble hearing, Mr. Snelson.

21   MR. SNELSON: Sorry, I believe it was a

22   two-area loss of load probability model, and that the

23   modeling assumption was that Ontario Hydro was

24   connected to a similar system via the interconnections.

25   And one of the problems of these sorts of analyses is

1   that if we were to be connected, model ourselves as

2   connected to the United States as one big pool, and

3   that all of their surface reserve was available to us,

4   then there would not be an appropriate sharing of the

5   reserve benefit.

6   The best model we could come up with was

7   that we could attribute a saving in reserve to

8   ourselves from the interconnection that was about equal

9   to the saving in reserve that we could contribute to

10   the other side. This is an equal sharing of the

11   benefit of interconnection.

12   Q. This figure seems to imply that the

13   interconnection assistance depends on the lead time.

14   Is this lead time the same as that which was used for

15   the load forecast uncertainty?

16   MR. TABOREK: A. It is the same

17   parameter, yes.

18   Q. When the lead time for load forecast

19   uncertainty was reduced from eight years to four years,

20   did you change the interconnection assistance

21   assumption?

22   A. No.

23   Q. Why was that?

24   A. Because we felt it was attempting

25   to -- you will note the changes that occur are small

1   and that it was not appropriate to try and discriminate

2   to that degree of detail with an analysis of this type.

3   You will notice that this particular

4   curve terminates in six years. Earlier, when we went

5   to six to eight years, we didn't adjust the 700

6   megawatt number. Then coming back to the four years,

7   you know, coming back from six to four, would give you

8   roughly 100 megawatts additional, if you believed this

9   analysis. And it was not really a strong basis, and it

10   would be a small benefit.

11   Q. If you could turn to page 43 of

12   Exhibit 137, that is 3.1 from the '81 reliability

13   criteria, doing a plot of Ontario versus Michigan

14   forecast errors, and I believe we have heard some

15   evidence about the correlations between various

16   systems.

17   Can you tell us how these correlations

18   were explicitly accounted for in deriving the 700

19   megawatt assumption?

20   MR. SNELSON: A. They were explicitly

21   accounted for in the sort of analysis that you saw on

22   page 42 of Exhibit 137, the previous figure you

23   referred us to, by assuming that the load forecast

24   uncertainty was modelled in each of the two areas.

25   I said it was a two-area loss of load

1   probability, so the assumption was that the load

2   forecast in our area was more or less correlated with

3   the load forecast uncertainty in the area to which we

4   are connected.

5   Clearly, the higher that degree of

6   correlation, the more likely that when we are in

7   trouble and need support over the interconnection, they

8   are also in trouble and haven't got any support, any

9   spare capacity to provide to us.

10

11

12

13

14

15

16

17

18

19

20

21

22

23

24

25   ...

1   [4:07 p.m.]   So, clearly, the higher the degree of

2   correlation, then the less will be the interconnection

3   support that can be relied upon when you really need

4   it.

5   Q.   So, in effect, that is your analysis

6   and out of that comes a judgment?

7   A.   Yes.

8   Q.   Was there any kind of simulation

9   performed or is this a pure judgment process?

10   A.   Well, this sort of analysis could be

11   termed 'a simulation.'

12   Q.   Okay. Was there any mechanical

13   simulation - any computer runs, anything like that?

14   A.   This is a computer run.

15   Q.   And is this an F&D run?

16   A.   No. I believe it was a loss of load

17   probability run. That is my recollection, but I would

18   have to check that.

19   Q.   All right. Now, has Hydro used the

20   results of a multi-area reliability study in looking at

21   the 700 megawatt assumption? You have mentioned --

22   A.   This is a two-area study; and since

23   two is part of multi, yes. But in the sense of more

24   than two, no.

25   Q.   Okay. Have they used a multi-run

1   reliability study?

2   A. I don't know what a multi-run

3   reliability study is.

4   Q. You use various definitions of the

5   study area and different runs in deriving the 700

6   megawatt assumption?

7   A. I don't recall any greater detail

8   than I have given you, I am afraid.

9   Q. Okay. I would like to turn now to

10   forecast uncertainty, with respect to NUGs and DSM.

11   Can you tell us how the DSM forecast is

12   represented in the F&D model runs?

13   MR. TABOREK: A. Excuse me, but can you

14   give the question again, please?

15   Q. Could you tell us how the DSM

16   forecast --

17   A. Demand management?

18   Q. Yes - the demand management forecast

19   is represented in the F&D model?

20   A. It subtracts from the basic to give

21   the primary load and then to the firm load. And of

22   particular importance, we make an assumption that the

23   absolute megawatt uncertainty in the basic load

24   forecast is not changed by demand management in going

25   to the primary.

1   Q.   Is the DSM forecast represented as

2   one or more generating units, for instance, or is it

3   represented as, say, a deduction from hourly loads?

4   A.   I believe it is a deduction in going

5   from the basic to the primary load, but I will check

6   that.

7   Q.   Okay. And could you also tell us

8   whether the deductions are median expected values or

9   some other values?

10   MR. SNELSON: A. The deductions of the

11   forecast values that are included in our demand

12   management projections?

13   Q.   They are the target values?

14   A.   They are the projected values, which

15   are the difference between the basic load forecast and

16   the primary load forecast.

17   Q.   Is any uncertainty in the DSM

18   forecast included in the F&D model runs?

19   A.   Only as described by Mr. Taborek,

20   where he said that the demand management is presumed

21   not to widen or to narrow the uncertainty band of the

22   basic load forecast.

23   Q.   I am trying to think through that. I

24   am not sure whether that answers my question.

25   I was wondering whether the demand

1   uncertainty was included. And you said to me that the

2   uncertainty in going from the basic to the primary

3   doesn't change.

4   Can I make a simple assumption that --

5   MR. TABOREK: A. If we state it very

6   simply, it is included, but it doesn't have a big

7   effect.

8   Q. Okay. Thank you.

9   How is the NUG forecast represented in

10   the F&D model run?

11   A. Well, the supply NUGs, of course, are

12   generators.

13   Q. Yes.

14   A. And the load some placement NUGs --

15   MR. SNELSON: A. Are part of the

16   deduction from the basic load forecast to the primary

17   load forecast.

18   Q. In the same way they would be a

19   deduction from the hourly loads?

20   A. Yes.

21   Q. Thank you.

22   With respect to the supply NUGs only, how

23   many units are accounted for?

24   MR. TABOREK: A. What do you mean by

25   "units"; how many generators?

1   Q.   Sure, yes.   How many NUG units?

2   A.   Well, they are modelled as small

3   generators.   .

4   Q.   Yes.

5   A.   I forget the actual size - so that

6   the benefits of small size are captured.

7   Q.   Could you attempt to find out for us?

8   A.   Yes.

9   Q.   Thank you.

10   And Mr. Taborek, while you are looking at

11   that, if you could also find the answer to these

12   questions: I am interested in the forced outage rates

13   assigned to the various units and --

14   A.   The NUG units?

15   Q.   Sorry?

16   A.   The various NUG units?

17   Q.   Yes.

18   A.   Ten per cent.

19   Q.   Ten per cent?

20   A.   Yes.

21   Q.   Okay.   And also, how the maintenance

22   requirements are represented.

23   A.   Yes.

24   Q.   I would also be interested as to

25   whether the NUGs are grouped according to any

1   particular classification, such as by technology, by

2   ownership or any other factors.

3   A.   Yes.

4   Q.   Thank you.

5   And I have the same question with respect

6   to uncertainties, whether the NUG uncertainty is

7   included in the F&D model run.

8   Would the answer be the same?

9   A.   Yes. I think we have answered both

10   of those.

11   Q.   Okay.

12   MR. SNELSON: A.   The NUGs are given a

13   forced outage rate, and that is the measure of

14   uncertainty of purchased NUGs that is given.

15   Q.   Okay. I would like to turn to the

16   subtopic of lead time, if you could look at page 41 of

17   Exhibit 137, which is Table 4.5 from Exhibit 87.

18   THE CHAIRMAN: Did you say 41?

19   MR. WATSON: Yes, page 41 of Exhibit 137.

20   THE CHAIRMAN: Right. I have got it

21   here.

22   MR. WATSON: Q.   The standard deviation

23   of the load forecast uncertainty is dependent on the

24   lead time.

25   In the F&D model, does the load forecast

1   uncertainty ramp up from some initial value to 8.8 per

2   cent from zero to four years?

3   MR. SNELSON: A. Yes, I believe it does.

4   Q. Is the standard deviation held

5   constant at 8.8 per cent for every year after four

6   years?

7   A. Yes.

8   Q. You don't need to turn it up because

9   I think we all remember it very well, Figure 5.1 from

10   the '91 reliability review.

11   I assume that there was a four-year lead

12   time assumption used in deriving the load forecast

13   uncertainty for these curves; is that fair?

14   MR. TABOREK: A. Yes.

15   Q. Okay. And I assume that is based on

16   the lead time for gas turbine; is that correct?

17   A. Yes.

18   Q. Okay. What statistics do you have to

19   determine four-year lead time?

20   A. I believe is reported in Chapter 14

21   of the Demand/Supply Plan, and it is, in essence, the

22   result of discussions with our engineering and supply

23   departments and their discussions with suppliers.

24   Q. Okay. Do you know if other utilities

25   are actually building gas turbines within this

1   four-year lead time?

2   MR. SNELSON: A. The construction time

3   of a gas turbine is given in figure 15-6 of Exhibit 3.

4   For a non-convertible and a normal cycle

5   gas turbine, assuming that all approvals have been

6   obtained - and this is a very significant point - the

7   acquisition time is given of one to two years.

8   Now, that does presume that the order

9   books of the manufacturers are not backed up as may

10   occur if all utilities run to buy combustion turbines

11   at the same time.

12   Q. And that might occur if there was a

13   high degree of correlation between various utilities?

14   A. That might, but you notice that is

15   one to two years.

16   The definition phase, which is the

17   obtaining of the specific site approval, and the

18   engineering work for a combustion turbine facility is

19   shown as having a lead time of one to three years with

20   a total of two to five. So then, four years is within

21   that two- to five-year range and slightly towards the

22   upper end of it.

23   Q. Okay. I was curious as to whether

24   you are aware of other utilities which had actually

25   built gas turbines within that lead time. Do you have

1   any information on that, or does Hydro have any

2   statistical data?

3   A.   Non-utility generators manage to buy   ·

4   combustion turbines and install them in less than that

5   time.

6   Q.   So you have information about NUGs as

7   opposed to other utilities then?

8   A.   We probably have information about

9   other utilities, but I don't have it available to me.

10   MR. TABOREK: A.   Our engineering and

11   supply departments would have made those checks in

12   developing these estimates.

13   Q.   Okay.

14   A.   We didn't, personally.

15   Q.   And to meet that lead time, of

16   course, I assume you would be helped by obtaining

17   pre-approvals if possible?

18   MR. SNELSON: A.   I think it is essential

19   that we have the approvals in principle of rationale

20   and need for the combustion turbine parts of our plan,

21   both the conventional combustion turbines and combined

22   cycle and IGCC to put us into the position of being

23   able to respond in a four-year lead time.

24   Q.   I assume you would also have to do

25   some pre-ordering of equipment?

1   A.   We should be able to order equipment

2   and have it installed in the four-year lead time,

3   presuming that the order books are not backed up at the

4   manufacturers.

5   Q.   Would the site have to be selected

6   before this four-year lead time?

7   A.   Possibly not.   The definition phase

8   is intended to cover the site-specific approval phase

9   and the preliminary engineering; and the site specific

10   approval phase does include site selection.

11   Now, that is probably sufficient time if

12   the selected site is one of the sites that we currently

13   own.   Combustion turbines can be added to our existing

14   generating plant sites with relatively modest impact.

15   It may not be sufficient time if it was necessary to go

16   out and acquire new sites.

17   This type of discussion as to exactly how

18   long these processes take would probably be better

19   addressed to Panel 8 on the fossil-fueled options.

20   Q.   Okay.   Panel, if you could turn to

21   page 44 of Exhibit 137; that is page 116 of Exhibit 87

22   and that mentions the role of the target reserve margin

23   in estimating avoided cost.

24

25   . . .

1   [4:22 p.m.]   Currently, does the "worth of adding a

2   CTU" from Figure 5.1 play a direct role in the

3   determination of avoided capacity costs?

4   A.   Direct, no; indirect, yes.

5   Q.   Could you elaborate on that, please,

6   Mr. Snelson?

7   A.   The capacity cost that is presumed

8   for quite a large part of the period in determining

9   avoided costs is the cost of adding a combustion

10   turbine unit to the system, and that is based on the

11   same estimate of the cost of a CTU as in this analysis.

12   We are going to talk about avoided costs

13   a lot in the next panel, I believe.

14   Q.   I understand. Currently, does the

15   same factor, the worth of adding a CTU, play a role in

16   evaluating avoided capacity costs in years before the

17   first major supply addition is needed?

18   A.   Yes.

19   Q.   And again, can you elaborate upon

20   that?

21   A.   In a lot of the avoided cost

22   calculations -- and again, I don't want to get into

23   Panel 3 matters --

24   Q.   I understand. If we can deal with it

25   just generally.

1   A.   The presumption is that non-utility

2   generation, demand management and hydraulic capacity

3   that is within the plan amounts will have deferred

4   combustion turbines, even in periods when we actually

5   don't plan to build combustion turbines, because we

6   have our demand management and non-utility generation

7   and hydraulic in the plan, which is the short-term, say

8   the next 10 years.

9   Q.   Now, currently, does the worth of

10   adding a CTU play a role in evaluating avoided capacity

11   costs in years before any new demand or supply

12   resources are required, specifically before the year

13   2000 in the low-demand scenario, and here I am

14   constrasting, in this question, demand management and

15   NUGs with the major supply options that you were just

16   addressing?

17   A.   I don't recall at the moment exactly

18   what the treatment is of capacity costs in the avoided

19   cost evaluation and the low demand scenario, but that

20   will be discussed in Panel 3.

21   Q.   There are five major supply plans.

22   Has Hydro run these plans in the F&D model and compared

23   the estimates of, for instance, voltage reductions and

24   other emergency actions?

25   A.   Which major supply plans are you

1   referring to?

2   Q.   The five in the D/SP.

3   A.   And the question was?

4   Q.   Has Hydro run these five plans in the

5   F&D model and compared the estimates of voltage

6   reductions and other emergency actions?

7   A.   I believe that what we have run is

8   some preliminary cases that are reported in Chapter 3

9   of the plan analysis, which I believe is Exhibit 6, and

10   the runs that are in Exhibit 87, which are essentially

11   based on Plan 15, which is the proposed plan.

12   I am not aware of runs having been done

13   on the other scenarios, the other plans. That's F&D

14   runs.

15   MR. WATSON: Thank you.

16   Mr. Chairman, that basically takes me

17   through reserve margin. I was going to turn to some of

18   the other major areas, but I notice that it is almost

19   4:30 and you wanted to stop at 4:30.

20   THE CHAIRMAN: How much longer do you

21   think you will be?

22   MR. WATSON: That is where the difficulty

23   comes in, in estimating this.

24   THE CHAIRMAN: I know. How many more

25   subjects do you have to cover, perhaps put it that way?

1   MR. WATSON: There are three major

2   subjects and a few minor subjects. The major subjects

3   are plant life extension, environmental issues and

4   plant performance. I am pretty sure that plant

5   performance issues, or at least a lot of them, may be

6   deferred to a later panel based on what Mr. Snelson was

7   saying this morning.

8   THE CHAIRMAN: You might be able to

9   discuss that with Mrs. Formusa, that might make it

10   easier for you to do your preparation, if you could

11   come to some agreement.

12   MR. WATSON: I will talk with Mrs.

13   Formusa as soon as we break.

14   THE CHAIRMAN: So you think you will be

15   part of the morning, anyway, on Monday?

16   MR. WATSON: It is a function of what

17   happens.

18   THE CHAIRMAN: Of course it is. I am not

19   trying to press you; I am just trying to get some rough

20   idea.

21   MR. WATSON: We could easily be all day

22   Monday, dealing with these questions. I don't want to

23   mislead you.

24   THE CHAIRMAN: Mr. Rodger, you are next?

25   MR. RODGER: Yes. Mr. Watson has

1   actually covered some of the ground that I intended to

2   cover, but I would anticipate still being around a day.

3   THE CHAIRMAN: Mr. Adams?

4   MR. ADAMS: Thank you, Mr. Chairman.

5   Unfortunately, counsel couldn't be here.

6   We expect, pending the outcome of this

7   cross-examination, particularly production forecast

8   reliability, and whatnot, to be approximately a day and

9   a half to two days.

10   THE CHAIRMAN: And you follow? I have

11   just forgotten now. You follow... ?

12   MR. ADAMS: We follow AMPCO and IPPSO

13   follows us, as I understand it.

14   THE CHAIRMAN: Where did we put Dofasco?

15   MS. MORRIS: After Ontario Natural Gas.

16   THE CHAIRMAN: All right. We will

17   adjourn until Monday morning at ten o'clock.

18   THE REGISTRAR: This hearing will adjourn

19   until Monday morning next at ten o'clock.

20   ---Whereupon the hearing was adjourned at 4:30 p.m. to
        be resumed on Monday, May 27, 1991, at 10:00 a.m.
